IPSc models - Part B

Welcome to my course on genome editing and engineering we are discussing about IPSc models currently. So, now, today we are going to discuss about the ZFNs and how they are used in creating IPSc models.

(Refer Slide Time: 00:50)

ZFNs

ZFNs have been used for the generation of engineered lines to study cell fate determination and improve iPSCs differentiation protocols (Hockemeyer et al., 2009), as well as to produce cell type-specific reporter systems for the investigation of disease pathogenesis (Zhang et al., 2016).

ZFNs-based genome editing was exploited for the correction of genetic mutations in patient-derived iPSCs or for insertion of known disease-relevant mutations in iPSCs derived from healthy allowing direct investigation of specific genomic alterations and disease phenotypes.

Hockemeyer et al. (2009). Efficient targeting of expressed and silent genes in human ESCs and iPSCs using zinc-finger nucleases. *Nat. Biotechnol.* 27, 851–857. doi: 10.1038/nbt.1562

8/5/2022

Zhang et al., (2016). Generation of GFAP::GFP astrocyte reporter lines from human adult fibroblast-derived IPS cells using zinc-finger nuclease technology. *Glia* 64, 63–75. doi: 10.1002/glia.22903

ZFNs have been used for generation of engineered lines to study cell fate determination and improve iPSCs differentiation protocols. As well as to produce cell type specific reporter systems for the investigation of disease pathogenesis. ZFN based genome editing was exploited for the correction of genetic mutation in patient derived iPSCs or for insertion of known disease relevant mutations in iPSCs derived from healthy patients allowing direct investigation of specific genomic alterations and disease phenotypes.

Generation of iPSCs and gene correction by nucleofection of ZFN constructs

Dermal fibroblasts, obtained from skin biopsies of patients with PD and healthy controls, were cultured. Reprogramming was adapted from Takahashi et al., 2007. Human iPSCs were cultured on mitomycin C (Tocris)-inactivated MEFs.

Gene correction was performed by nucleofection of ZFN constructs targeting LRRK2 (Sigma). 50 µg/ml G418 (PAA) 2 µM ganciclovir (Sigma)-resistant colonies were picked and clonally expanded on MEFs.

They demonstrated that neurons differentiated from iPSCs derived from patients with PD harboring LRRK2 G2019S exhibit multiple phenotypes including reduced neurite outgrowth and increased sensitivity to stress.

They performed gene correction by nucleofection of ZFN constructs targeting LRRK2.

By using gene-corrected isogenic cultures and the introduction of the mutation into a control iPSC line they discovered the genes that contribute to PD-associated phenotypes in cultured mDA neurons induced by LRRK2 G2019S.

They concluded that hiPSC-derived neurons with LRRK2 G2019S which exhibit Parkinsonian neurodegeneration can be rescued by gene correction of the LRRK2 mutation by nucleofection of ZFN constructs

8/5/2022

M9Weinhardt et al. (2013). *Cell Stem Cell* 12, 354–367. doi: 10.1016/j.stem.2013.01.008

The generation of iPSCs and gene correction by nucleofection of ZFN constructs. Dermal fibroblasts, obtained from skin biopsies of patients with a PD and healthy control were cultured, reprogramming was adapted from Takahashi et al. Human iPSCs were cultured on mitomycin C inactivated MEFs.

Gene correction was performed by nucleofection by which ZFN constructs targeting LRKK 2. They demonstrated that neurons differentiated from iPSCs derived from patients with Parkinson's disease harboring LRKK 2, G2019S exhibit multiple phenotypes including reduced neurite outgrowth and increased sensitivity to stress.

They performed the gene correction by nucleofection of ZFN constructs targeting this LRKK 2 gene. By using gene corrected isogenic cultures and the introduction of the mutation into a control iPSC line, they discovered the genes that contribute to Parkinson's disease associated phenotypes in cultured mDA in neurons induced by LRKK2 G2019S.

And after all these probing, they concluded that human induced pluripotent stem cell derived neurons with LRKK G2019S which exhibit parkinsonian neuron neuro degeneration can be rescued by gene correction of the LRKK2 mutation by nucleofection of ZFN constructs. For a detailed methods and procedure for conducting these experiment, you may refer to cell stem cell 12 page number 354.

In the absence of translational in vitro disease models Tauopathies such as frontotemporal dementia (FTD) remain incurable.

The microtubule-associated protein tau (MAPT) gene, play an important role in FTD pathogenesis.

Verheyen et al. used zinc finger nucleases to introduce two MAPT mutations into healthy donor induced pluripotent stem cells (iPSCs).

The IVS10+16 mutation increases the expression of 4R tau, while the P301S mutation is pro-aggregant.

Whole-transcriptome analysis of MAPT IVS10+16 neurons reveals neuronal subtype differences, reduced neural progenitor proliferation potential, and aberrant WNT/SHH signaling.

Notably, these neurodevelopmental phenotypes could be recapitulated in neurons from patients carrying the MAPT IVS10+16 mutation.

Moreover, the additional pro-aggregant P301S mutation revealed additional phenotypes, such as an increased calcium burst frequency, reduced lysosomal acidity, tau oligomerization, and neurodegeneration. This series of iPSCs could serve as a platform to unravel a potential link between pathogenic 4R tau and FTD.

8/5/2022

TALENs in iPSC

They reported that genetic targeting of a therapeutic cassette expressing the CSF2RA^{coop} transgene from the ubiquitous CAG promoter into the AAVS1 locus corrects the disease phenotype in herPAP-specific iPSCs and their progeny.

In an in vitro model, targeted iPSCs and thereof derived macrophages showed stable CSF2RA expression and restored GM-CSF dependent signaling and functionality such as STAT5 phosphorylation or GM-CSF uptake.

Certainly, extensive further studies particularly in animal models will be required to underline the feasibility, safety and efficacy of gene corrected iPSC-derived macrophages to be used as a potential therapy for herPAP.

Let us now discuss about a TALENs in iPSc, the genetic targeting of a therapeutic cassette expressing the CSF2RA coop transgene from the ubiquitous CAG promoter into the AAVS1 locus corrects the disease phenotype in herPAP-specific iPSCs and their progeny.

In an in vitro model targeted iPSCs and thereof derived macrophages showed stable CSF2RA expression and restored GM-CSF dependent signaling and functionality such as STAT5 phosphorylation or GM-CSF uptake. Certainly, extensive studies further particularly in animal models will be required to underline the feasibility, safety, and efficacy of gene corrected iPSCs derived macrophages to be used as a potential therapy for a herPAP.

(Refer Slide Time: 06:29)

Hereditary pulmonary alveolar proteinosis (herPAP) is a rare, but life threatening lung disorder characterized by the inability of alveolar macrophages to clear the alveolar airspaces from surfactant phospholipids. herPAP is caused by a defect in the CSF2RA gene coding for the GM-CSF receptor alpha-chain (CD116).

High magnification micrograph of pulmonary alveolar proteinosis. Lung, H&E stain. The images show the characteristic airspace filling with focally dense hyaline globs, known as "chatter" or "dense bodies".

BY Nephron
https://commons.wikimedia.org/wiki/File:Pulmonary_alveolar_proteinosis_-_3-_high_mag.jpg
8/5/2022

In the absence of therapeutic options, Kuhn and associates attempted a cell and gene therapy for its treatment.

They tried intrapulmonary transplantation of gene-corrected macrophages derived from herPAP-specific induced pluripotent stem cells (herPAP-iPSC) employing TALENs.

The targeted insertion of a codon-optimized CSF2RA-cDNA driven by the hybrid cytomegalovirus (CMV) early enhancer/chicken beta actin (CAG) promoter into the AAVS1 locus led to robust expression of the CSF2RA gene in gene-edited herPAP-iPSCs as well as thereof derived macrophages.

M9L2

39

So, herPAP or hereditary pulmonary alveolar proteinosis is a rare, but life-threatening lung disorder which is characterized by the inability of alveolar macrophage to clear the alveolar airspaces from surfactant and phospholipids. HerPAP is caused by a defect in the CSF2RA gene coding for the GM-CSF receptor alpha chain or CD116.

So, here you can see high magnification micrograph of pulmonary alveolar proteinosis. The images show the characteristics airspace filling with focally dense hyaline globs known as chatter or dense bodies. In the absence of therapeutic options, Kuhn and associates attempted a cell and gene therapy for its treatment. They tried intrapulmonary transplantation of gene corrected macrophages derived from herPAP specific induced pluripotent stem cells employing TALENs.

The targeted insertion of a codon optimized CSF2RS-cDNA driven by the hybrid cytomegalovirus CMV early enhancer chicken beta actin CAG promoter into the AAVS1 locus led to robust expression of the CSF2RA gene, in gene edited herPAP iPSCs as well as thereof derived macrophages.

Reprogramming of iPSCs

For the clinical application of iPSCs it was important to demonstrate that reprogramming could be achieved without stably integrating the KSOM factors into the genome of the somatic cell.

Such factor-free iPSCs were generated by independent methods such as:

- the excision of reprogramming factors using the Cre/LoxP (Soldner et al., 2009) or
- the piggyBack system (Kaji et al., 2009; Woltjen et al., 2009),
- by avoiding integration of the reprogramming factors all together using non-integrating viruses (Fusaki et al., 2009), episomal vectors (Yu et al., 2009) or
- direct transfection of the reprogramming factors as either mRNA (Warren et al., 2010) or protein (Kim et al., 2009).

Reprogramming of iPSCs, for the clinical application of iPSCs it was important to demonstrate that reprogramming could be achieved without stably integrating the KSOM factors into the genome of the somatic cell. Such factor free iPSCs were generated by independent methods such as the excision of programming factors using the Cre/LoxP, the piggyBack system by avoiding integration of the programming factors all together using non integrating viruses and direct transfection of the reprogramming factors as either mRNA.

(Refer Slide Time: 10:28)

What worked well for mouse turned out to be inefficient in human cell reprogramming initially.

Several technical improvements have to be made to optimize hiPSC production from somatic cells. These includes

- i. reprogramming protocols,
- ii. culture conditions and
- iii. iPSC characterization procedures to test for the pluripotency of newly isolated iPSCs.

Today, the technology is largely optimized, streamlined and increasingly more accessible to laboratories without prior stem cell experience and nowadays iPSC derivation, maintenance and differentiation are a popular and widely used research tool in all aspects of biomedical research.

One of the most attractive feature of the iPSC technology is that it allows the isolation of patient-derived cells carrying the genetic alterations that cause the particular disease.

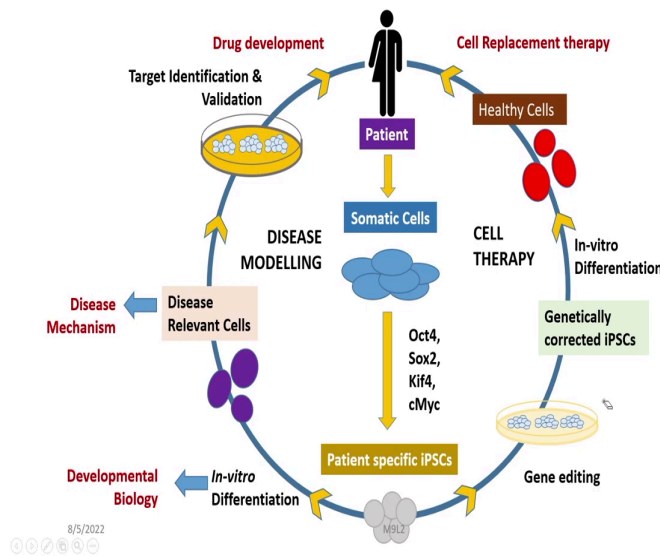

Such cells provide an readily available experimental system to study pathogenesis of the disease in an *in vitro* system and to devise potential therapeutic strategies.

What worked well for a mouse however turned out to be inefficient in human cell reprogramming initially. Several technical improvements have to be made to optimize human induced pluripotent stem cell production from somatic cells. This included reprogramming protocols, culture conditions, and iPSC characterization procedures to test for the pluripotency of newly isolated iPSCs.

Today the technology is largely optimized, streamlined and increasingly more accessible to laboratories without prior stem cell experience and nowadays iPSC derivation, maintenance and differentiation are a popular and widely used research tool in all aspects of biomedical research.

One of the most attractive features of the iPSC technology is that, it allows the isolation of patient derived cells carrying the genetic alterations that cause the particular disease. Such cells provide a readily available experimental system to study pathogenesis of the disease in an in vitro system and to devise potential therapeutic strategies.

(Refer Slide Time: 11:35)

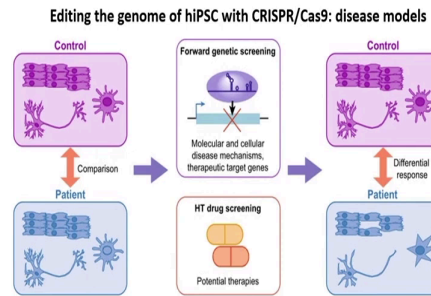

So, in this picture we can see a patient from which the somatic cells are isolated and then these are reprogrammed using the OSKM factors; and thereby, we can get patient specific induced pluripotent stem cell. This may be either taken for in-vitro differentiation and used for developmental biology studies or for disease relevant cells for understanding the disease mechanisms.

And used further for target identification and validation in drug development and the knowledge would be applied finally on the patient. On the left-hand side, you can see that these patient specific iPSCs can be used for gene editing.

And then we may genetically correct the iPSCs and go for in-vitro differentiation and generate healthy cells which can be used for cell replacement therapy. So, in either case we have a huge potential of iPSCs in association with CRISPR Cas9 technologies, we may also develop animal models using these technologies.

(Refer Slide Time: 13:31)

Application of iPS models of disease to high throughput screening. Cells derived from patients with disease and healthy controls can be used to generate disease-relevant cell types, which can be phenotypically compared with each other. Such cells can be generated in sufficient numbers to be able to perform whole genome genetic screens to identify molecular and cellular mechanisms of disease and therapeutic targets, and also for high throughput drug screening to identify compounds that may be able to revert the disease phenotype. Differences between patient-derived and control cells can be used to identify potential therapeutic targets or agents

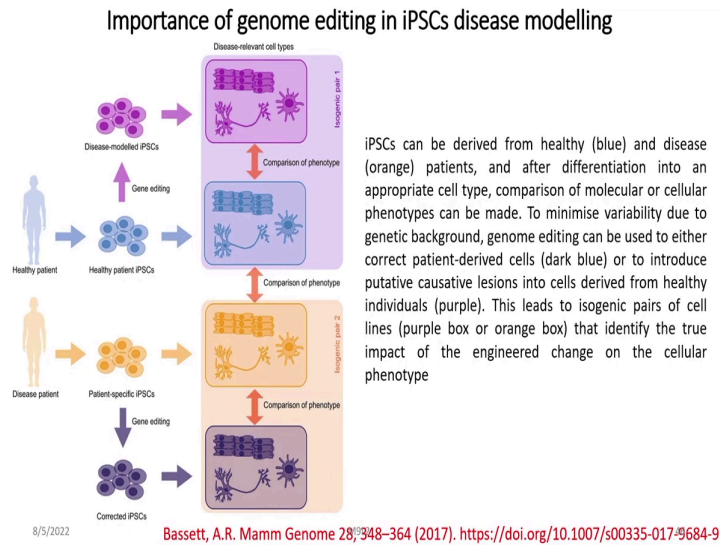

8/5/2022

Bassett, A.R. *Mamm Genome* 28:348–364 (2017). <https://doi.org/10.1007/s00335-017-9684-9>

So, let us discuss about the editing the genome of human induced Pluripotent stem cells with CRISPR Cas9 for developing disease models. So, application of the induced pluripotent stem cell model of disease to high throughput screening is possible. Cells derived from patients with disease and healthy control can be used to generate disease relevant cell types which can be phenotypically compared with each other.

Such cells can be generated in sufficient numbers to be able to perform whole genome genetic screens to identify molecular and cellular mechanisms of disease and therapeutic targets. And also, for high throughput drug screening to identify compounds that may be able to revert the disease phenotype. Differences between patient derived and controlled cells can be used to identify potential therapeutic targets or agents.

(Refer Slide Time: 14:32)

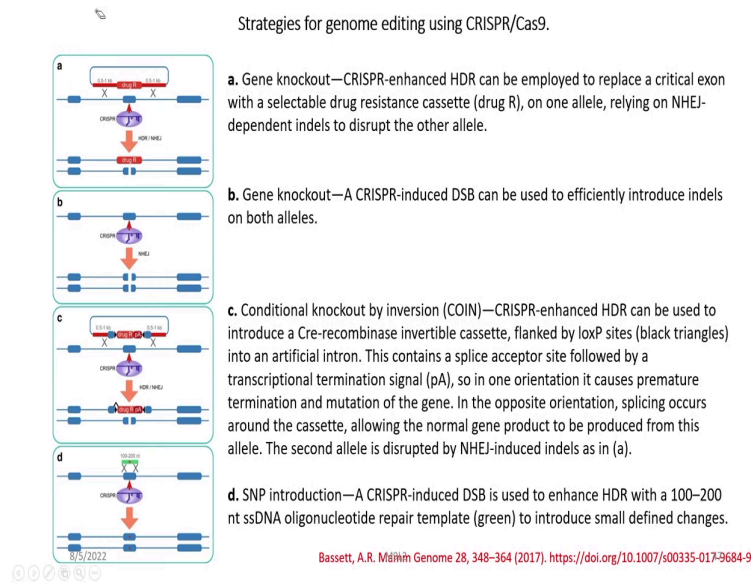

So, we see that genome editing in iPSC for disease modelling has a lot of scope and importance. Here, we have a healthy patient and a diseased patient giving rise to healthy patient iPSCs and patient specific iPSCs from with the help of gene editing we can go for disease model iPSCs or we can go for corrected iPSCs.

And then in the case of disease model iPSCs, we can go for disease relevant cell types and go for comparison of the phenotypes. Similarly, also in the case of corrected iPSC we can compare between the two populations. So, iPSCs can be derived from healthy as well as a diseased patient as shown over here.

And to minimize the variability due to genetic background genome editing can be used to either correct the patient derived cells or to introduce putative causative lesions in the cells derived from healthy individuals. This leads to isolating pairs of cell lines that identify the true impact of the engineered change on the cellular phenotype.

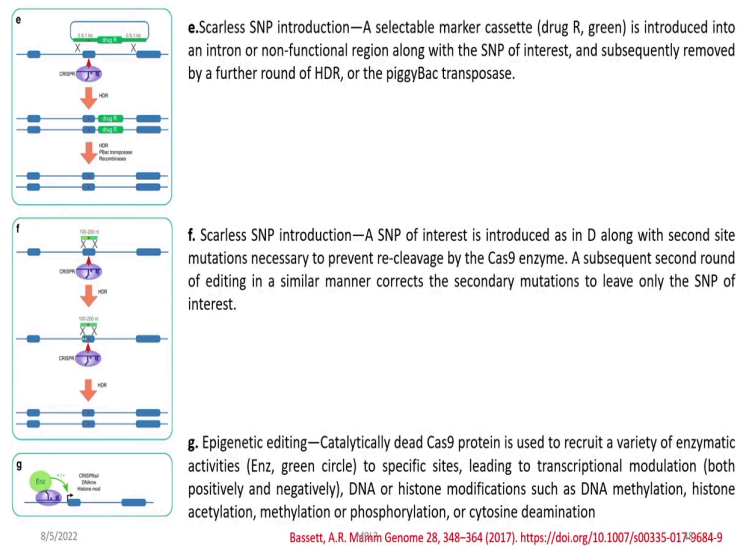

(Refer Slide Time: 16:02)

What are the various strategies for genome editing using CRISPR Cas9 these are all known to you we can go for a gene knockout or gene knockin or conditional knockouts by inversion (COIN). So, this is a CRISPR enhanced HDR can be used to introduce a Cre-recombinase invertible cassette flanked by loxP sites into an artificial intron.

This contains a splice acceptor site followed by a transcriptional termination signal PA. So, in one orientation it causes premature termination and mutation of the gene, in the opposite orientation splicing occurs around the cassette allowing the normal gene products to be produced from this allele. The second allele is disrupted by non-homologous and joining induced indels as in the figure a.

(Refer Slide Time: 17:08)

We can also go for SNP introduction using CRISPR Cas9 technology and also with advancements we can today produce scarless SNP introduction or epigenetic editing using date Cas9. These are all these known to you from prior discussions, what is important using iPSCs is the quality of the iPSCs.

(Refer Slide Time: 17:23)

iPSC quality control and recognition by morphological differences

The comparability of stem cell lines from different individuals is needed for iPSC lines to be used in therapeutics [1]. Among critical quality procedures, the following can be distinguished:

Short tandem repeat analysis

This is the comparison of specific loci on the DNA of the samples. It is used in measuring an exact number of repeating units. One unit consists of 2 to 13 nucleotides repeating many times on the DNA strand.

A polymerase chain reaction is used to check the lengths of short tandem repeats. The genotyping procedure of source tissue, cells, and iPSC seed and master cell banks is recommended.

Identity analysis—The unintentional switching of lines, resulting in other stem cell line contamination, requires rigorous assay for cell line identification.

Zakrzewski, W., Dobrzyński, M., Szymonowicz, M. et al. Stem cells: past, present, and future. *Stem Cell Res Ther* 10, 68 (2019). <https://doi.org/10.1186/s13287-019-1165-5>

8/5/2022

M9L2

49

So, we have to have quality control of iPSCs and recognition of the morphological differences. The comparability of stem cell lines from different individuals is needed for iPSC lines to be used in therapeutics among critical quality procedures the following are

important or distinguishable Short tandem repeat analysis. This is the comparison of specific loci on the DNA of the samples it is used in measuring an exact number of repeating units.

One unit consists of 12 to 13 nucleotides repeating many times on the DNA strand, A polymerase chain reaction is used to check the lengths of short tandem repeats. The genotyping procedures of source tissues cells and iPSC seed and master cell banks is recommended. Identity analysis is also one important quality control aspect, the unintentional switching of lines resulting in other stem cell line contamination requires rigorous assay for cell line identification.

(Refer Slide Time: 18:39)

Residual vector testing—An appearance of reprogramming vectors integrated into the host genome is hazardous, and testing their presence is a mandatory procedure. It is a commonly used procedure for generating high-quality iPSC lines. An acceptable threshold in high-quality research-grade iPSC line collections is ≤ 1 plasmid copies per 100 cells.

During the procedure, 2 different regions, common to all plasmids, should be used as specific targets, such as EBNA and CAG sequences [1]. To accurately represent the test reactions, a standard curve needs to be prepared in a carrier of gDNA from a well-characterized hPSC line.

For calculations of plasmid copies per cell, it is crucial to incorporate internal reference gDNA sequences to allow the quantification of, for example, ribonuclease P (RNaseP) or human telomerase reverse transcriptase (hTERT).

Zakrzewski, W., Dobrzyński, M., Szymonowicz, M. et al. Stem cells: past, present, and future. *Stem Cell Res Ther* 10, 68 (2019). <https://doi.org/10.1186/s13287-019-1165-5>

8/5/2022

M9L2

50

Residual vector testing is also very very important an appearance of reprogramming vectors integrated into the host genome is hazardous, and testing their presence is a mandatory procedure. It is a commonly used procedure for generating high quality iPSC lines an acceptable threshold in high quality research grade iPSC line collection is less than or maximum equal to 1 plasmid copies per 100 cells; so, it is less than 1 percent.

During the procedure 2 different regions common to all plasmids should be used as specific targets such as EBNA and CAG sequences. To accurately represent the test reactions, a standard curve needs to be prepared in a carrier of CR GDNA from a well characterized hPSC line. For calculations of plasmid copies per cell it is crucial to incorporate internal reference GDNA sequences to allow the quantification of, for example, ribonuclease P or human telomerase reverse transcriptase's.

(Refer Slide Time: 19:42)

Karyotype—A long-term culture of hESCs can accumulate culture-driven mutations [2]. Because of that, it is crucial to pay additional attention to genomic integrity. Karyotype tests can be performed by resuscitating representative aliquots and culturing them for 48–72 h before harvesting cells for karyotypic analysis.

If abnormalities are found within the first 20 karyotypes, the analysis must be repeated on a fresh sample. When this situation is repeated, the line is evaluated as abnormal. Repeated abnormalities must be recorded.

Viral testing—When assessing the quality of stem cells, all tests for harmful human adventitious agents must be performed (e.g. hepatitis C or human immunodeficiency virus). This procedure must be performed in the case of non-xeno-free culture agents.

Zakrzewski, W., Dobrzyński, M., Szymonowicz, M. et al. Stem cells: past, present, and future. *Stem Cell Res Ther* 10, 68 (2019). <https://doi.org/10.1186/s13287-019-1165-5>

8/5/2022

Viral testing, when assessing the quality of stem cells all tests for harmful human adventitious agents must be performed. This procedure must be performed in the case of non-xeno free culture agents.

(Refer Slide Time: 20:38)

Flow cytometry—This is a technique that utilizes light to count and profile cells in a heterogeneous fluid mixture. It allows researchers to accurately and rapidly collect data from heterogeneous fluid mixtures with live cells. Cells are passed through a narrow channel one by one. During light illumination, sensors detect light emitted or refracted from the cells. The last step is data analysis, compilation and integration into a comprehensive picture of the sample.

Phenotypic pluripotency assays—Recognizing undifferentiated cells is crucial in successful stem cell therapy. Among other characteristics, stem cells appear to have a distinct morphology with a high nucleus to cytoplasm ratio and a prominent nucleolus. Cells appear to be flat with defined borders, in contrast to differentiating colonies, which appear as loosely located cells with rough borders [3].

It is important that images of ideal and poor quality colonies for each cell line are kept in laboratories, so whenever there is doubt about the quality of culture, it can always be checked according to the representative image. Embryoid body formation or directed differentiation of monolayer cultures to produce cell types representative of all three embryonic germ layers must be performed. It is important to note that colonies cultured under different conditions may have different morphologies [4].

Zakrzewski, W., Dobrzyński, M., Szymonowicz, M. et al. Stem cells: past, present, and future. *Stem Cell Res Ther* 10, 68 (2019). <https://doi.org/10.1186/s13287-019-1165-5>

(Refer Slide Time: 22:15)

Histone modification and DNA methylation—Quality control can be achieved by using epigenetic analysis tools such as histone modification or DNA methylation. When stem cells differentiate, the methylation process silences pluripotency genes, which reduces differentiation potential, although other genes may undergo demethylation to become expressed [5].

It is important to emphasize that stem cell identity, together with its morphological characteristics, is also related to its epigenetic profile [6, 7]. According to Brindley [8], there is a relationship between epigenetic changes, pluripotency, and cell expansion conditions, which emphasizes that unmethylated regions appear to be serum-dependent.

Zakrzewski, W., Dobrzyński, M., Szymonowicz, M. et al. Stem cells: past, present, and future. *Stem Cell Res Ther* 10, 68 (2019).

Bacteriology—Bacterial or fungal sterility tests can be divided into culture- or broth-based tests. All the procedures must be recommended by pharmacopoeia for the jurisdiction in which the work is performed.

Single nucleotide polymorphism arrays—This procedure is a type of DNA microarray that detects population polymorphisms by enabling the detection of subchromosomal changes and the copy-neutral loss of heterozygosity, as well as an indication of cellular transformation.

The SNP assay consists of three components. The first is labelling fragmented nucleic acid sequences with fluorescent dyes. The second is an array that contains immobilized allele-specific oligonucleotide (ASO) probes. The last component detects, records, and eventually interprets the signal.

Zakrzewski, W., Dobrzyński, M., Szymonowicz, M. et al. Stem cells: past, present, and future. *Stem Cell Res Ther* 10, 68 (2019).

iPSC banking, European bank for induced pluripotent stem cells was established to address the increasing demand by iPSC researchers. For quality control disease relevant research grade iPSC lines, data and cell services. This kind of banking services reduces the work of researchers to a large extent. A second project phase was launched on March 2019 incorporating key members of the first project phase.

And it continues to distribute this is relevant in high quality iPSCs along with comprehensive dataset. The quality control of iPSCs are very very important which we have discussed in the earlier section. And this European bank for induced pluripotent stem cells try to maintain the highest quality of iPSCs and provide to the researcher network.

Workflow of EBiSC and Taiwan Human Disease iPSC Consortium

8/5/2022

M912 Huang et al., Journal of Biomedical Science 26(1) DOI:10.1186/s12929-019-0578-6

So, similar to this European bank for induced pluripotent stem cells there is also a bank in Taiwan called the Taiwan Human Disease iPSC consortium. And you can see the workflow of both the repositories in these flow diagram. They are donor samples and then the iPSC generation takes place in the second phase.

There is a programming, reprogramming methods and the culture history are recorded. Expansion of the cells are carried out under feeder free culture system, then iPSCs made from academic institutions commercial companies may also be deposited to this European bank.

Then characterizations are there Roslin Cell Sciences, NIBSC and depositor center cooperate to offer the characterizations which include the sterility, viability, viral screening, cell phenotype, chromosomal stability, pluripotent potential, and the genetic identity which we discussed at length in the earlier slides. And then finally, these are sent for banking or for the repository. A cell line is frozen in about 50 vials, 2 vials as backup at Roslin Cell Sciences, 10 percent of vials at mirror banks, there are many other similar banks.

And Fraunhofer IBMT and 90 percent of highest at EC ACC is serve as main storage and distribution center to the customers. In Taiwan human disease iPSC consortium similar approach is there with the donor samples which are coded. And then these are tested for chromosomal abnormalities, and then they are reprogrammed by a Sendai virus induction. And then transgene free tested cell shifted from feeder dependent culture to feeder free culture, iPSC is a frozen as working cell bank backup.

Then performed Affymetrix SNP 6.0 array for SNP genotyping and genetic variation. Then these are also characterized using various methods and they are frozen in 6 to 10 vials at master cell bank and working cell bank for each clone. A quality control a sterility authenticity and post thawed viability. And then certificate of analysis is also issued, informational cell lines posted on website and these are accessible by all researchers in Taiwan.

So, there are many such iPSC banks worldwide and some of these are accessible to researchers globally. Majority of them are government owned and they are also private owned, like fuji film cellular dynamics international which is owned by Fujifilm. And there are also certain owned by certain universities like the university of Wisconsin and you can see the huge investment involved in building up of these iPSC banks.

Considerations for iPSC disease models

The important considerations while using iPSCs as a disease model,

- i. whether the disease is monogenic or polygenic,
- ii. the penetrance of the mutation,
- iii. the age of onset,
- iv. whether differentiation into an appropriate cell type is possible, and
- v. if there is an appropriate phenotypic readout at a molecular or cellular level.

It is critical with any iPSC disease model to pinpoint a cell type in which the disease manifests, to be able to differentiate effectively into these cells, and to identify a molecular or cellular phenotypic readout of the disease state.

Differentiation protocols are now available to efficiently generate a large variety of lineages, and many others are being developed using cocktails of small molecule inhibitors or transcription factor overexpression (Cohen and Melton 2011; Mertens et al. 2016; Murry and Keller 2008).

Such protocols often result in a mixed population, and purification of the desired cells by for example fluorescence-activated cell sorting (FACS) using an appropriate marker or reporter gene can be used to enrich the population of interest (Horikiri et al. 2017; Wu et al. 2016a, b).

Another important consideration with the use of iPSCs in disease modelling is that these cells and their differentiated derivatives often resemble those of foetal origin (Hrvatin et al. 2014), and therefore the age of onset of any disease becomes relevant.

Bassett, A.R. *Mitochondria* Genome 28, 348–364 (2017). <https://doi.org/10.1007/s00335-017-9684-9>

We have to take into consideration certain things for generating iPSC disease models. these are the following important considerations for using iPSC as a disease model. Number one whether the disease is monogenic or polygenic, if the penetration of the mutation is known, the age of onset. Whether differentiation into an appropriate cell type is possible, and if there is an appropriate phenotypic read out at a molecular or cellular level. It is important for any iPSC disease model to pinpoint a cell type in which the disease manifests to be able to differentiate effectively into these cells and to identify a molecular or cellular phenotypic read out of the disease state. Differentiation protocols are now available to efficiently generate a large variety of lineages and many others are being developed using cocktails of small molecule inhibitors or transcription factor over expression.

Such protocols often result in a mixed population and purification of the desired cells. For example, by fluorescence activated cell sorting using an appropriate marker or reporter gene can be used to enrich the population of interest. Another important consideration with the use of iPSCs in disease modeling is that these cells and their differentiated derivatives often resemble those of foetal origin and therefore, the age of onset of any disease becomes relevant.

Limitations and developments

Although the benefits of iPSC technology are undeniable, there are some limitations in their use for modelling certain disease states. Such in vitro models have immense power in terms of scalability, and being able to apply techniques such as high throughput genetic or pharmacological screening that would not be possible or be technically difficult in an in vivo setting.

However, they are limited in their ability to recapitulate complex tissue architecture both in terms of the complexity of cell types as well as their spatial organization, making analysis of many physiological or system-level phenotypes challenging.

Highly defined co-culture systems can be beneficial in some situations, for instance where the effects are non-cell autonomous, or rely on cell-cell signaling.

Most genetic diseases are due to a small contribution from a large number of genes. Such polygenic disorders are inherently more difficult to study than monogenic diseases, as the penetrance and severity of the phenotype due to any single mutation are lower.

Genetic targeting strategies in combination with efficient differentiation protocols will provide a powerful tool for autologous iPSC-based therapies in the future.

Bassett, A.R. *Mitochondria* Genome 28, 348–364 (2017). <https://doi.org/10.1007/s00335-017-9684-9>

In spite of these various developments there are certain limitations, the benefit of iPSC technology are undeniable. As you can see from the various potential and the discussion we have made regarding certain diseases. There are some limitations in the use for modeling certain disease states as well. Such in vitro models have immense power in terms of scalability and being able to apply techniques such as high throughput genetic or pharmacological screening that would not be possible technically and difficult in an in vivo setting.

However, they are limited in their availability in their ability to recapitulate complex tissue architecture both in terms of the complexity of cell types as well as their spatial organization. Making analysis of many physiological or system level phenotypes challenging. Highly defined co culture systems can be beneficial in some situations for instance where the effects are non-cell autonomous or rely on cell-cell signaling.

Most genetic diseases are due to a small contribution form from a large number of genes. Such polygenic disorders are inherently more difficult to study than monogenic diseases as the penetrance and severity of the phenotype due to any single mutations are lower. Genetic targeting strategies in combination with efficient differentiation protocols will provide a powerful tool for autologous iPSC-based therapies in the future.

SUMMARY

Generation and application of hiPSCs. Somatic cells are harvested from patients and reprogrammed into patient-specific hiPSCs. The hiPSCs can then be differentiated into different cell types, such as cardiomyocytes, smooth muscle cells, and endothelial cells, which can be used in different applications.

To sum up we can see here a patient from whom the patient specific somatic cells has been isolated and reprogrammed using various factors whose which may be OSCM or also including Nanog, Lin 28. And it generates patient specific human induced pluripotent stem cells.

And these may be further differentiated into different type of cells and used for various applications like tissue engineering, regenerative medicine, drug development screening. And disease modeling which is the focus of these particular major focus of this particular lecture. So, the potential applications of human induced pluripotent stem cells and gene editing combined together is quite huge as we have discussed in these particular lectures.

Potential applications of hiPSCs and gene editing.

Therapeutic potential of hiPSC technology combined to gene editing and tissue engineering.

Figure sourced from Gähwiler EKN, Motta SE, Martin M, Nugraha B, Hoerstrup SP and Emmert MY (2021) *Front. Cell Dev. Biol.* 9:639699, who has adapted the same from senior medical art, licensed under a Creative Commons Attribution 3.0 Unported License.

1. hiPSCs are generated from the reprogramming of patient-specific healthy or diseased somatic cells.
2. Gene editing tools, such as CRISPR-Cas9, generates isogenic cell lines harboring specific genetic mutations in the healthy hiPSCs, and also correct disease-causing mutations in the patient populations. The generated hiPSCs is then re-differentiated into various cell types and/or tissue.
3. Differentiated isogenic hiPSCs is used in drug development/screening processes, biobanking, disease modeling, and tissue engineering. On the other side, the differentiated diseased hiPSCs could be further employed for disease modeling and drug development/screening. When genetic mutations are corrected, then cell-based therapy and tissue regeneration purposes can be applied.

61

In conclusion we need to remember that human induced pluripotent stem cells are generated from the reprogramming the patient specific healthy or diseased somatic cells. Gene editing tools like CRISPR Cas9, ZFN, TALENs, generate isogenic cell lines, harboring specific genetic mutations in the healthy induced pluripotent stem cells. And also can correct disease causing mutations in the patient population, the generated human induced pluripotent stem cells are then re differentiated into various cell types and or tissues.

Differentiated isogenic human iPSCs are used in drug development screening process, disease modeling and tissue engineering and they are also preserved in biobanks for supply to various researchers. On the other side the differentiated disease human iPSCs could be further employed for disease modeling and drug development screening. When genetic mutations are corrected, then cell based therapy and tissue regeneration purposes can be also achieved.
