Lecture 46
Car Following Theory-3

Welcome to module F lecture 3. In this lecture, we shall continue our discussion about car following theory.

(Refer Slide Time: 0:24)

The slide is titled "Recap of Lecture F.2" in blue text. Below the title, there is a bulleted list of topics covered in the previous lecture. At the bottom right of the slide, there is a small video inset showing Professor Bhargab Maitra speaking. The footer of the slide contains the IIT Kharagpur logo, the text "IIT Kharagpur | Traffic Engineering | Module F", and the page number "2".

- General motors theory
 - ✓ First generation model
 - ✓ Second generation model
 - ✓ Third generation model
 - ✓ Fourth generation model
 - ✓ Fifth generation model

In lecture 2, I explained to you various models first generation, second generation, third generation, fourth generation, and fifth generation models all these models which were developed by General Motors, I explained to you fifth generation model is the most generalized model and all the other four models are special cases of the generalized fifth generation model. While I explained to you the basic idea or the concept and the model form, I said that we will continue our discussion with an example problem. So, that is what we are going to do now.

(Refer Slide Time: 1:16)

General Motors Theory

Problem: The leading vehicle and following vehicle are travelling with a speed of 15 m/s and space headway of 20 m. At $t = 2$ seconds, lead vehicle accelerates by 1.5 m/s^2 for 2 seconds, then decelerates by 1 m/s^2 for 2 seconds. Simulate the behaviour (acceleration, speed and position) of the following vehicle for every 0.5 seconds (scan interval = 0.5 s) interval using General Motors' Car following model

Assume the parameters $l=1$, $m=0$, sensitivity coefficient $(\alpha_{l,m}) = 12$, reaction time = $\Delta t = 1 \text{ s}$

General Motors Theory

Solution:

Generalized CF model

$$\ddot{x}_{n+1}(t + \Delta t) = \frac{\alpha_{l,m} [\dot{x}_{n+1}(t + \Delta t)]^m}{[x_n(t) - x_{n+1}(t)]^l} [\dot{x}_n(t) - \dot{x}_{n+1}(t)]$$

Parameters $l=1$, $m=0$, sensitivity coefficient $(\alpha_{l,m}) = 12$

$$\ddot{x}_{n+1}(t + \Delta t) = \frac{12}{x_n(t) - x_{n+1}(t)} [\dot{x}_n(t) - \dot{x}_{n+1}(t)]$$

General Motors Theory

t (s)	\ddot{x}_1 (m/s ²)	\dot{x}_1 (m/s)	x_1 (m)	\ddot{x}_2 (m/s ²)	\dot{x}_2 (m/s)	x_2 (m)	$\dot{x}_1 - \dot{x}_2$ (m/s)	$x_1 - x_2$ (m)
0	0.00	15.00	20.00	0.00	15.00	0.00	0.00	20.00
0.5	0.00	15.00	27.50	0.00	15.00	7.50	0.00	20.00
1	0.00	15.00	35.00	0.00	15.00	15.00	0.00	20.00
1.5	0.00	15.00	42.50	0.00	15.00	22.50	0.00	20.00
2	1.50	15.00	50.00	0.00	15.00	30.00	0.00	20.00
2.5	1.50	15.75	57.69	0.00	15.00	37.50	0.75	20.19
3	1.50	16.50	65.75	0.00	15.00	45.00	1.50	20.75
3.5	1.50	17.25	74.19	0.45	15.00	52.50	2.25	21.69

For leading vehicle,
 $u_1(2)$ = Speed at t i.e. 2s;
 $a_1(2)$ = vehicle acceleration or deceleration at t i.e. 2s;
 $x_1(2)$ = distance covered till t i.e. 2 s
 T = time or scan interval i.e. 0.5 s

LV Speed at $t = 2.5 \text{ s}$: $u_1(2) = 15 \text{ m/s}$; $a_1(2) = 1.5 \text{ m/s}^2$; $T = 2.5 - 2 = 0.5 \text{ s}$

$$v = u + aT = 15 + 1.5(2.5-2) = 15.75 \text{ m/s}$$

So, let us take an example problem, the leading vehicle and following vehicles are traveling with the speed of 15 meters per second. So, both are traveling at the same speed and with a space headway of 20 meter. So, initial speeds both vehicles are same spacing or space headway is 20 meter then at time t equal to 2 seconds the lead vehicle accelerates by 1.5 meters per second square for 2 seconds.

And then further decelerates by 1 meter per second squared for the next 2 seconds. With this background, what we want we want to simulate the behavior, behavior means the response in terms of acceleration speed also the position of the following vehicle for every 0.5 second interval. So, every 0.5 second interval we want to update, so, you can call it also a scan interval.

Using General Motors car following model where l is 1, m is 0, you know already what is l what is m and the sensitivity coefficients α l m equal to 12 the reaction time is 1 second. So, this is reaction time that is 1 second and we want the update at 0.5 seconds interval. That is the scan interval.

So, how to calculate it before we show you the calculation before I explain you the steps, let us look at the generalized model car following model as proposed by General Motors is the fifth-generation model. So, this model form is known to you the response in terms of acceleration deceleration at time t plus Δt depends on the α a constant which is already given.

This is the speed of the following vehicle at time t plus Δt but since m equal to 0 this term will get omitted then divided by $x_n(t) - x_{n+1}(t)$. So, if the distance headway between space headway between vehicle n and $n+1$ to the power l , l is taken as 1. So, m is 0, l is 1. So, it actually indicates that this is the third-generation model as proposed by General Motors multiplied by relative speed of two vehicles.

So, \dot{x}_n at time t minus \dot{x}_{n+1} at time t . Now, remember that time t what is happening that the response we are trying to model after time Δt which is the reaction time this is very important. So, this simplified form of this generalized model as per the third-generation model given coefficient indicate giving values indicate that it is actually a third-generation model. So, I have written it.

Now, using this model we shall calculate all the values which are asked in the example problems or question that what will be the acceleration what will be the speed what will be the position of the following vehicle at scan interval of 0.5 seconds. Here I have shown the

calculation for the first 3 and half seconds 3.5 seconds simply because otherwise it will be too lengthy.

So, I wanted to show it only for 3.5 seconds and explaining the calculation, then I will show you the entire calculation. Let us go column wise we want the scan interval of 0.5 seconds. So, start with 0 and 0, 0.5, 1, 1.5, 2, 2.5, 3, and 3.5 like that it will go for 15 minutes. Because that is what we eventually want or for even longer time. Now so, that is understood x double dot one leading vehicle acceleration.

So, we know at time t equal to 0, it is 0 for the first four interval time t 0.5 1 1.5 at 2 seconds it starts doing the acceleration. So, at 2 seconds the value will be 1 for the next 2 seconds. So, that means 1.2, 2.5, 3 and 3.5 All will be actually 1.5 seconds look at this problem carefully at t equal to 2 seconds and lead vehicle starts acceleration accelerating at 1.5 meters per second squared for 2 seconds.

So, when it is exactly t equal to 2 acceleration starts. So, at that time, so, at t equal to 2 we have taken the acceleration. So, these are basically inputs. So, similarly, in subsequent time also when I show you the full table you will see this is given input. So, first column is given input second column is again given input third column is the speed.

Now, this can be calculated initially we said that it is traveling at 15 meter per second both the leading vehicle and the following vehicle. So, now we are doing the leading vehicle calculation and leading vehicle we know it starts accelerating from t equal to 2 seconds onwards.

So, at t equal to 2 seconds also it will be 15 meter per second speed, because that is the time when it starts accelerating. So, how to calculate the remaining values I am showing you one calculation suppose at t equal to 2.5 how we can get the x_1 dot leading vehicle speed. So, the cell which we are going to calculate I have indicated it in green.

We are going to use a simple formula which you all know v equal u plus aT . So, here we are talking t equal to 2.5 seconds what is going to happen? So, when you are talking about trying to calculate the value at t equal to 2.5 seconds at 0.5 seconds scan interval as I have indicated here that as capital T so, that means our u is at 2 seconds.

So, what is the initial speed at t equal to 2 seconds 15 meters per second is given what is the acceleration at t equal to 2 seconds 1.5 meters per second square and what is my this interval T capital T it is nothing but the scan interval always it will be 0.5 but this is the time we have

here between 2.5 seconds and 2 seconds that 0.5 seconds. That is why I have shown the calculation here. The remaining is simple.

So, v equal to u plus aT, you put the u value as 15 meter per second, a as 1.5 meters per second squared and capital T equal 0.5 seconds or 2.5 minus 2. So, you get 15.75. So, this cell you get and now using the same approach you can calculate all the remaining cells in the same column. So, column 1, input column 2 is also direct input, column 3, we know how to calculate.

(Refer Slide Time: 10:12)

General Motors Theory

t (s)	\dot{x}_1 (m/s ²)	\dot{x}_1 (m/s)	x_1 (m)	\ddot{x}_2 (m/s ²)	\dot{x}_2 (m/s)	x_2 (m)	$\dot{x}_1 - \dot{x}_2$ (m/s)	$x_1 - x_2$ (m)
0	0.00	15.00	20.00	0.00	15.00	0.00	0.00	20.00
0.5	0.00	15.00	27.50	0.00	15.00	7.50	0.00	20.00
1	0.00	15.00	35.00	0.00	15.00	15.00	0.00	20.00
1.5	0.00	15.00	42.50	0.00	15.00	22.50	0.00	20.00
2	1.50	15.00	50.00	0.00	15.00	30.00	0.00	20.00
2.5	1.50	15.75	57.69	0.00	15.00	37.50	0.75	20.19
3	1.50	16.50	65.75	0.00	15.00	45.00	1.50	20.75
3.5	1.50	17.25	74.19	0.45	15.00	52.50	2.25	21.69

For leading vehicle,
 $u_1(2)$ = Speed at t i.e. 2s;
 $a_1(2)$ = vehicle acceleration or deceleration at t i.e. 2s;
 $x_1(2)$ = distance covered till t i.e. 2 s
T = time or scan interval i.e. 0.5 s

LV Distance at t = 2.5 s:

$u_1(2) = 15 \text{ m/s}; a_1(2) = 1.5 \text{ m/s}^2; T = 2.5 - 2 = 0.5 \text{ s}$

$s = uT + \frac{1}{2} aT^2 = 15 * (2.5 - 2) + \frac{1}{2} * 1.5 * (2.5 - 2.0)^2 = 7.69 \text{ m}$

Distance $x_1(2.5) = x_1(2) + s = 50 + 7.69 = 57.69 \text{ m}$

IIT Kharagpur | Traffic Engineering| Module F

6

Now next go to column four. So, in this slide I am going to explain you how we can calculate a cell in Column four. Here, I am going to again explain you that at t equal to 2.5 seconds, how we are going to calculate the value of x1 all leading vehicle till now. So, leading vehicle acceleration is known we calculated leading vehicle then the speed and we want to calculate the x1 the distance from the reference point.

So, how we can calculate the distance. So, this was like initially as it was, it is said that the initially it is said that the space headways 20 meter. So, we are considering the x1 at t equal to 0 it is 20 meter, then we are going to use again a simple formula s equal to uT plus half of aT squared a is the acceleration.

Now, in all these calculation initial calculation, the a is 0 because you can see the x dot values are 0 and therefore, wherever a will be other than 0 this half aT square also will come, let us take the generalized s equal to uT plus aT squared and try to see how we can calculate the x1 value at t equal to 2.5 seconds.

So, when we are talking at trying to calculate the distance as t equal to 2.5 seconds, we are trying to calculate how much distance it will move in between 2 and 2.5 seconds. So, within that 0.5 seconds, how much distance it will move. So, what is the u , u will be taking a speed at time t equal to 2 that is 15 meter per seconds.

a is again at time T equal to 2 what is the acceleration 1.5 meters per second square and what is the T value is the difference between 2.5 and 2 scan interval so, that is 0.5. So, s equal to uT plus half aT square a value is known, u is known capital T is known. So, you get the s as 7.69, then what will be the distance x_1 it will be at 2 seconds it was 50.

So, in between 2 and 2.5 seconds at 2.5 meters traveled another 7.69 meter. So, the total is 50 plus 7.69 57.69. So, you know how to calculate the cell. So, once you know this, you can calculate all the cells in column x_1 . So, we are through with cell one input, cell two as input cell three calculation, cell four calculation.

(Refer Slide Time: 13:21)

General Motors Theory

t (s)	\ddot{x}_1 (m/s ²)	\dot{x}_1 (m/s)	x_1 (m)	\ddot{x}_2 (m/s ²)	\dot{x}_2 (m/s)	x_2 (m)	$\dot{x}_1 - \dot{x}_2$ (m/s)	$x_1 - x_2$ (m)
0	0.00	15.00	20.00	0.00	15.00	0.00	0.00	20.00
0.5	0.00	15.00	27.50	0.00	15.00	7.50	0.00	20.00
1	0.00	15.00	35.00	0.00	15.00	15.00	0.00	20.00
1.5	0.00	15.00	42.50	0.00	15.00	22.50	0.00	20.00
2	1.50	15.00	50.00	0.00	15.00	30.00	0.00	20.00
2.5	1.50	15.75	57.69	0.00	15.00	37.50	0.75	20.19
3	1.50	16.50	65.75	0.00	15.00	45.00	1.50	20.75
3.5	1.50	17.25	74.19	0.45	15.00	52.50	2.25	21.69

FV Acceleration at t = 3.5 (this is t + Δt in GM model) s: $\dot{x}_1(2.5) = 15.75$
m/s; $\dot{x}_2(2.5) = 15$ m/s; $x_1(2.5) = 57.69$ m; $x_2(2.5) = 37.5$ m

$$\ddot{x}_{n+1}(t + \Delta t) = \frac{12}{x_n(t) - x_{n+1}(t)} [\dot{x}_n(t) - \dot{x}_{n+1}(t)]$$

$$\ddot{x}_{n+1}(2.5 + 1) = \frac{12}{57.69 - 37.5} * (15.75 - 15) = 0.45 \text{ m/s}^2$$

IIT Kharagpur | Traffic Engineering | Module F 7

Now we go to cell five here we are actually trying to calculate the response acceleration deceleration whatever it is. Obviously, you know you put to this formula you know when both vehicles are traveling at the same speed obviously first the first 0 at 0.5 at 1 and at 1.5 even at 2 also the you know the deceleration whatever will happen let us that we can also calculate but the initially it will be all 0.

The actual the response will acceleration deceleration that response will be there. Once the vehicle in front of the leading vehicle start accelerating or decelerating. So, let us try to see how we can calculate a cell let us take the cell corresponding to time t equal to 3.5 seconds. Now, this is the cell the green one that we are going to calculate.

So, what will be the acceleration or deceleration of the following vehicle at time t equal to 3.5 seconds, but as you know if we are trying to calculate the cell it is actually in this equation t plus delta t that is the t here because we are taking the time clock. So, at 3.5 seconds what is going to happen? That is the response is happening after 1 second because that is what the reaction time.

So, delta t is 1 second. So, we will take the values like the speed at 2.5 seconds, because the reaction time is 1 second. So, x1 dot at 2.5 we will take we know that it is 15.75 x2 dot at 2.5 it is we know that it is 0 sorry it is 15 meter per second then x1 2.5 this is 57.69 x2 2.5 the following vehicle it is 37.50 then we go to this equation third generation general motor model we know it is 12 by xn t minus xn plus 1 t.

So, this will be simply x_1 and x_2 you can consider. So, the x_1 values are known also the \dot{x}_1 and \dot{x}_2 plus 1 all we are taking a time $t = 2.5$ second what is the value that is the basis for calculating the response after Δt time the reaction time. So, $t + \Delta t$ is the time clock. So, you calculate it as 0.45 meters per second square. So, exactly in the same way now, you can calculate all the cells in this column \dot{x}_2 that means, the response of the following vehicle. So, next it will be \dot{x}_2 and x_2 .

(Refer Slide Time: 16:45)

General Motors Theory

t (s)	\ddot{x}_1 (m/s ²)	\dot{x}_1 (m/s)	x_1 (m)	\ddot{x}_2 (m/s ²)	\dot{x}_2 (m/s)	x_2 (m)	$\dot{x}_1 - \dot{x}_2$ (m/s)	$x_1 - x_2$ (m)
0	0.00	15.00	20.00	0.00	15.00	0.00	0.00	20.00
0.5	0.00	15.00	27.50	0.00	15.00	7.50	0.00	20.00
1	0.00	15.00	35.00	0.00	15.00	15.00	0.00	20.00
1.5	0.00	15.00	42.50	0.00	15.00	22.50	0.00	20.00
2	1.50	15.00	50.00	0.00	15.00	30.00	0.00	20.00
2.5	1.50	15.75	57.69	0.00	15.00	37.50	0.75	20.19
3	1.50	16.50	65.75	0.00	15.00	45.00	1.50	20.75
3.5	1.50	17.25	74.19	0.45	15.00	52.50	2.25	21.69

FV Speed at $t = 3.5$ s: $u_2(3) = 15$ m/s; $a_2(3) = 0$ m/s²; $T = 3.5 - 3 = 0.5$ s

$v = u + aT = 15 + 0 \cdot (3.5 - 3) = 15$ m/s

$s = uT + \frac{1}{2}aT^2 = 15 \cdot (3.5 - 3.0) + \frac{1}{2} \cdot 0 \cdot (3.5 - 3.0)^2 = 7.5$ m

Distance $x_2(3.5) = x_2(3) + s = 45 + 7.5 = 52.50$ m

For leading vehicle,
 $u_1(3)$ = Speed at t i.e. 3s;
 $a_1(3)$ = vehicle acceleration or deceleration at t i.e. 3s;
 $x_1(3)$ = distance covered till t i.e. 3 s
 T = time or scan interval i.e. 0.5 s

IIT Kharagpur | Traffic Engineering | Module F

8

So, we are going to explain you now how you can calculate \dot{x}_2 and x_2 let us take that both you know we are trying to calculate at 3.5. Again, the basic equation is $v = u + aT$. Simply you can get this value. So, at 3.5 means 0.5 second interval, that is the scan interval. So, we will take the u value and a value at t equal to 3 seconds. And obviously, Δt again capital T is again 0.5 seconds that is the scan interval.

So, you can get v you can get s , s you can get using this formula $uT + \frac{1}{2}aT^2$. So, once you get this s so, what will be then 45 plus s and once you get the speed that is going to be used for the calculation of x_2 if you know the other values. So, that way the whole calculation is explained.

(Refer Slide Time: 17:50)

General Motors Theory

t (s)	\ddot{x}_1 (m/s ²)	\dot{x}_1 (m/s)	x_1 (m)	\ddot{x}_2 (m/s ²)	\dot{x}_2 (m/s)	x_2 (m)	$\dot{x}_1 - \dot{x}_2$ (m/s)	$x_1 - x_2$ (m)
0	0.00	15.00	20.00	0.00	15.00	0.00	0.00	20.00
0.5	0.00	15.00	27.50	0.00	15.00	7.50	0.00	20.00
1	0.00	15.00	35.00	0.00	15.00	15.00	0.00	20.00
1.5	0.00	15.00	42.50	0.00	15.00	22.50	0.00	20.00
2	1.50	15.00	50.00	0.00	15.00	30.00	0.00	20.00
2.5	1.50	15.75	57.69	0.00	15.00	37.50	0.75	20.19
3	1.50	16.50	65.75	0.00	15.00	45.00	1.50	20.75
3.5	1.50	17.25	74.19	0.45	15.00	52.50	2.25	21.69

Relative Speed at $t = 3.5 \text{ s} = \dot{x}_1 - \dot{x}_2 = 17.25 - 15.0 = 2.25 \text{ m/s}$
 Distance headway at $t = 3.5 \text{ s} = x_1 - x_2 = 74.19 - 52.5 = 21.69 \text{ m}$

IIT Kharagpur | Traffic Engineering | Module F
9

Now, what is remaining is really \dot{x}_1 minus \dot{x}_2 and x_1 minus x_2 that is very simple because if we know \dot{x}_1 also you know \dot{x}_2 also you will know the speed of lead vehicle and following vehicle at any time t . So, we can find out what is the relative speed we also know x_1 we also know x_2 .

So, we can calculate at any time interval t what is going to be the value of x_1 minus x_2 I have shown it here for time t equal to 3.5 seconds. So, you can see that, so, that way all the cells now, you are through with all the columns. So, 1 is input 2 is input 3 onwards 3, 4, 5, 6, 7, 8, 9 all these columns how we calculate I explained.

So, here I am showing the complete table for the first 15 seconds not shown the complete table really they initially I have shown here up to 8 seconds and then the last 14.5 and 15 seconds you can even calculate and try to match what is important for you to note that at 2 second it starts accelerating.

So, the x_1 dot value at 2 seconds is taken as 1.5 and then it is said after 2 seconds it start decelerating. So, again at 4 second onwards, the value is taking us minus 1. So, note that at 2 second also it will be 0 because it is 2 seconds on it starts accelerating at 2 seconds. So, at 2 seconds it starts accelerating. So, the value is 1.5 not 0. So, similarly after 2 second means, at 4 seconds, we will start taking the minus 1 the remaining all calculation I have explained.

(Refer Slide Time: 19:38)

Now, here I am trying to show how the curve will look like x axis is the time y axis is the acceleration. So, the black line shows the leading vehicle for how the acceleration is always changing over time. And the red one shows for the following vehicle which we tried to model using the car following model actually we tried to capture using car following model.

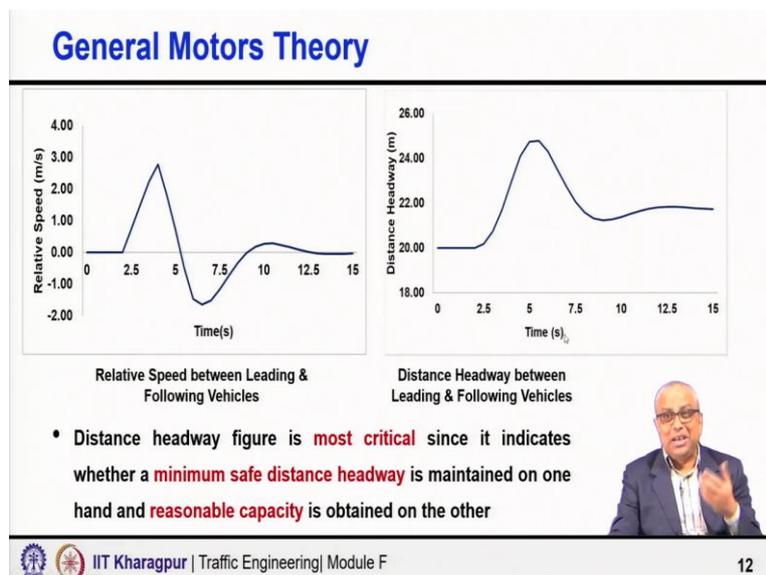

So, you can see that it is showing interesting to see that we are actually able to model the response in terms of acceleration or deceleration, because here you know, in this segment it is acceleration and in this segment it is deceleration. So, how the response is happening and all is the following vehicle lags behind the lead vehicle.

So, it starts doing the acceleration then it is also start doing after a lag and it can decelerate, so, it also starts reducing and finally decelerate also some gap. So, it is trying to catch up here it is shown the speed profile of leading and following vehicle, you can also see the speed is

increasing, here also after some time it is increasing, it is reducing this also is then the following vehicle is also reducing the speed.

But it is not just a shift in time but the overall pattern and values are also very different. So, the pattern here is the black line pattern and the red line pattern is different here also the pattern for the variation for the red black line and the pattern what is shown as the red line, they are not same not just lateral shifted, but the values are also different but suddenly it is going to respond. So, if the leading vehicle lead vehicle is accelerating the following vehicle is also trying to accelerate but not exactly in the same way. There is of course a gap and but also not exactly the same manner.

(Refer Slide Time: 21:47)

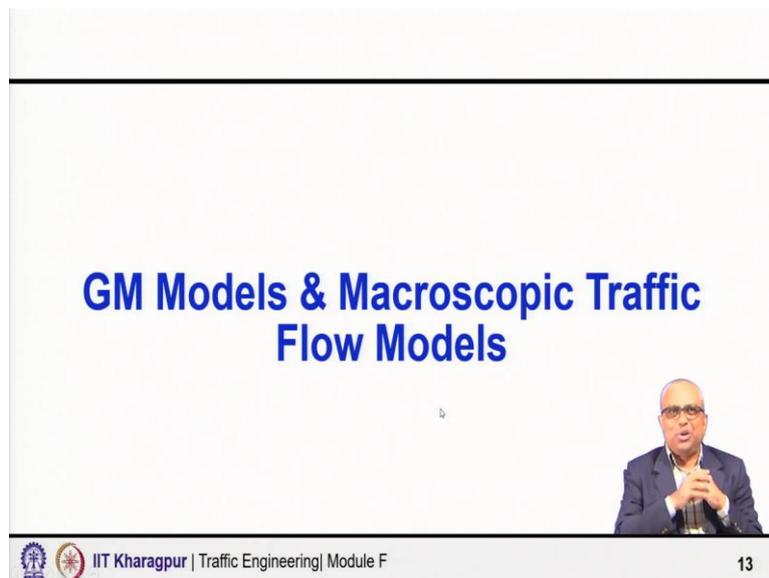

Here we are trying to show the relative speed and here it is the distance headway very interesting distance headway the relative speed also shows that it is always trying to catch up. So, relative speed is suddenly the front vehicle or lead vehicle accelerate. So, the speed relative speed becomes higher but then immediately in the response the following vehicle also start doing the acceleration. So, that the it can catch up.

So, it is always trying to catch up trying to catch up and you know the relative speed almost ending with some oscillation it is trying to keep the relative speed 0 trying to do that. But there is a pattern is different lag is different, there will be time lag also in the response, the nature of response is also not exactly the way the lead vehicle behaved the following vehicle will behave exactly in the same manner not like that, you get seeing that everywhere.

So, this is what it is and the distances headway figure is most critical. What I have shown here, since it indicates whether a minimum safe distance headway is maintained at one end the reasonable capacity in a larger context overall context a reasonable capacity is obtained on the other hand.

So, the distance headway that is why it is very critical because it influence the safety it will tell you that whether the response is going to be safe it is that that safety is very important because it depends on the space headway and also the finally the capacity also depends on the headway or inverse of headway is 1 by headway is actually the distance headway is actually the density. The density influences the throughput the capacity also will depend on that and all traffic parameters it is going to be influenced by this behavior. So, the space headway or the distance headway is very, very important. And we are able to get that we are able to model that.

(Refer Slide Time: 24:17)

So, with this now, let us go to another topic. It is the General Motors model, which is the microscopic model and the macroscopic traffic model what you have studied earlier Greenfield's model Greenberg's model and so, on. Is there any relation? Are they can they be linked? That is the part we are going to discuss now.

(Refer Slide Time: 24:43)

GM Models & Macroscopic Traffic Flow Models

- Port of New York researchers developed macroscopic model of speed (Greenberg's Model):

$$\mu = \mu_0 \ln \frac{k_j}{k}$$

μ = space mean speed; k = density; μ_0 = optimum speed; k_j = jam density

- Optimum speed is defined as that speed which existed when traffic flow level is at capacity
- Researchers found that numerical values for α_0 (3rd microscopic GM model) and μ_0 (Greenberg's macroscopic model) were almost identical for different highway facilities

GM Models & Macroscopic Traffic Flow Models

- It was suspected that there was a relationship between 3rd microscopic GM model and Greenberg's macroscopic model

- 3rd microscopic GM model: $\ddot{x}_{n+1}(t + \Delta t) = \frac{\alpha_0}{[x_n(t) - x_{n+1}(t)]^2} [\dot{x}_n(t) - \dot{x}_{n+1}(t)]$

- Integrating it with respect to t (steady state condition exists) we get,

$$\dot{x}_{n+1} = \alpha_0 [\ln(x_n - x_{n+1})] + C_1$$

- If μ (space mean speed) is substituted for \dot{x}_{n+1} and $1/k$ (k = density) is substituted for $x_n - x_{n+1}$, then

$$\mu = \alpha_0 \ln \frac{1}{k} + C_1$$

GM Models & Macroscopic Traffic Flow Models

- Let $\alpha_0 \ln C_2$ be substituted for C_1 , then

$$\mu = \alpha_0 \ln \frac{1}{k} + \alpha_0 \ln C_2 \quad \mu = \alpha_0 \ln \frac{C_2}{k}$$

- When $k = k_j$, $\mu = 0$; k_j = jam density

$$0 = \alpha_0 \ln \frac{C_2}{k_j}$$

- Solving for C_2 yields: $\ln \frac{C_2}{k_j} = 0$ $\frac{C_2}{k_j} = 1$ $C_2 = k_j$

- Substituting $C_2 = k_j$:

$$\mu = \alpha_0 \ln \frac{k_j}{k} \quad \dots\dots(9.15)$$

So, what happened port of New York researchers develop macroscopic model of speed Greenberg's model you can see μ equal to $\mu_0 \ln \frac{k_j}{k}$ by k μ is the space mean speed obviously k is the density μ is here the optimum speed that is the speed at capacity speed at capacity and k_j is the jam density.

$$\mu = \mu_0 \ln \frac{k_j}{k}$$

Now, optimum speed as I have said it is the speed when existed when the traffic flow level is that capacity. Now, interestingly rather very interestingly researcher found that numerical value of α_0 in the third-generation model you know this term α_0 in the third-generation model and the value of μ_0 here the Greenberg's model.

This is Greenberg's model μ_0 they were almost identical for different highway facilities that data came and they found what is the value of μ_0 in Greenberg's model and then in General Motors third generation model what is α_0 these values are almost identical for different highway facilities.

Then they started thinking is it just a sheer coincidence or is really there is they are same what is the μ_0 here in Greenberg's model and what is α_0 in the third-generation microscopic model proposed by General Motors are the same thing because one is macroscopic one is microscopic.

So, they started doing the research or started working further investigations and eventually they found a connection that I am going to explain you how they got. So, let us take the third generation microscopic model remember it is microscopic model and whereas, Greenberg is macroscopic.

$$\ddot{x}_{n+1}(t + \Delta t) = \frac{\alpha_0}{[x_n(t) - x_{n+1}(t)]^1} [\dot{x}_n(t) - \dot{x}_{n+1}(t)]$$

So, can we get from this model can we really get this third generation General Motors model can we get the Greenberg's model that was the attempt. So, what if you integrate this with respect to stay t under steady state condition then it is x double dot acceleration. So, you get speed x dot n plus 1 α_0 and this whole term obviously becomes log of $\ln x_1 - x_n$ minus x_n plus 1.

$$\dot{x}_{n+1} = \alpha_0 [\ln(x_n - x_{n+1})] + C_1$$

Because here in the denominator it was x_n are they omitted theta term here because for simplicity. So, x_n minus x_{n+1} so, it comes \ln of log of this plus a constant term. Now, if μ is the space mean speed in Greenberg's model is substituted for this x_{n+1} . What is x_{n+1} it is speed.

So, if we consider that the space mean speed that is the way the whole traffic speed is behaving under steady state conditions so, this x_{n+1} can be replaced by μ quite possible and also what is x_n minus x_{n-1} it is the distance headway spacing or space headway.

So, 1 by that is what density macroscopic parameter density. So, we do that x_{n+1} replacing by μ and this x_n minus x_{n-1} we are replacing by 1 by k because 1 by distance headway is the density plus c_1 we have moved one step one small step we have proceeded. Still it does not look yes 1 by k has come but u_{n+1} . So, now let us see what we can do with the C_1 .

$$\mu = \alpha_0 \ln \frac{1}{k} + C_1$$

C_1 also can be written it is a constant it can be written as $\alpha_0 \ln C_2$. So, what was C_1 a constant. We can substitute that and we can write it like another constant α_0 . Here also α_0 is there. So, we write α_0 and $\ln C_2$ otherwise we can write because after all it is a constant. So, what do you get here? μ equal to $\alpha_0 \ln C_2$ by k . The form has come already it has come it has already come it now looks like something like a greenback model. Of course, there is still we do not know what is C_2 where α_0 is there. whether how can know that that is really μ_0 . That we do not know. Because our this form is μ_0 .

But this overall looks has come these look very similar. μ equal to $\alpha_0 \ln C_2$ by k . Now, our next step was to understand what is the C_2 how we can get the value of C_2 . Because here it is actually k_j by k is that C_2 is equal to k_j what they did let us take when k equal to k_j a jam density, then obviously μ equal to 0 speed is 0 .

So, you take speed is 0 , k equal to k_j then $\alpha_0 \ln C_2$ by k . Now this, what it tells you, this is 0 , α_0 is again a constant. So, obviously it indicates that C_2 is actually k_j So, we got it μ equal to $\alpha_0 \ln k_j$ by k μ equal to $\mu_0 \ln k_j$ by k the only difference is here is μ_0 and here it is α_0 even by comparing these two also you can now say this must be μ_0 and α_0 was the same. You got the other form but those still let us see if we can even bring with a little bit of more analysis, if we can bring α_0 as μ_0 .

$$\mu = \alpha_0 \ln \frac{k_j}{k}$$

(Refer Slide Time: 32:33)

GM Models & Macroscopic Traffic Flow Models

- Since $q=uk$, multiplying both sides by k of equation $\mu = \alpha_0 \ln \frac{k_j}{k}$

$$q = k\alpha_0 \ln \frac{k_j}{k}$$
- Differentiating $dq/dk = 0$ when $k = k_0$ (k corresponding to the maximum flow = k_0)

$$\frac{dq}{dk} = \alpha_0 \ln \frac{k_j}{k_0} + \alpha_0 k_0 \left[\frac{k_0}{k_j} \left(-\frac{k_j}{k_0^2} \right) \right]$$

$$0 = \alpha_0 \ln \frac{k_j}{k_0} - \alpha_0$$
- Solving for k_0 : $\ln \frac{k_j}{k_0} = 1$; $\frac{k_j}{k_0} = e$; $k_0 = \frac{k_j}{e}$
- Substituting $\mu = \mu_0$ and $\frac{k_j}{e}$ for k_0 in equation 9.15

IIT Kharagpur | Traffic Engineering | Module F 17

GM Models & Macroscopic Traffic Flow Models

- Let $\alpha_0 \ln C_2$ be substituted for C_1 , then

$$\mu = \alpha_0 \ln \frac{1}{k} + \alpha_0 \ln C_2 \quad \mu = \alpha_0 \ln \frac{C_2}{k}$$
- When $k=k_j$, $\mu = 0$; k_j = jam density

$$0 = \alpha_0 \ln \frac{C_2}{k_j}$$
- Solving for C_2 yields: $\ln \frac{C_2}{k_j} = 0$ $\frac{C_2}{k_j} = 1$ $C_2 = k_j$
- Substituting $C_2 = k_j$:

$$\mu = \alpha_0 \ln \frac{k_j}{k} \quad \dots\dots(9.15)$$

IIT Kharagpur | Traffic Engineering | Module F 16

What was done you know q equal to uk flow equal to speed into density at macroscopic level, speed flow density are related. So, let us multiply both sides by k . So, k into μ speed flow and here k into $\alpha_0 \ln k$ by k same α_0 only we have taken the k multiplied by k both sides.

Now, if we differentiate this flow with respect to q by that is what the capacity. So, at capacity we know k equal to k_0 optimum density when the dq/dk equal to 0 then whatever is the k value that is the optimum density at capacity. So, dq/dk you take to the derivative make it 0 and when you make it 0 and already we have taken know that, that k equal to k_0 in that case.

So, if you solve you get actually k_0 equal to k_j by e fine. Now, go back to this equation 9.15 μ equal to $\alpha_0 \ln \frac{k_j}{k}$ by k . Substitute μ equal to μ_0 and k_0 because that is the capacity point that we are trying to understand. What happens in this equation. So, μ equal to μ_0 and k_0 we are replacing by k_j by e .

(Refer Slide Time: 34:28)

GM Models & Macroscopic Traffic Flow Models

$$\mu_0 = \alpha_0 \ln \frac{k_j}{k} \quad \mu_0 = \alpha_0$$

- Substituting $\mu_0 = \alpha_0$ in equation 9.15

$$\mu = \mu_0 \ln \frac{k_j}{k} \text{ (Greenberg macroscopic model) } \dots\dots(9.16)$$

- The bridge between 3rd microscopic GM model and the Greenberg macroscopic model was a very important discovery

IIT Kharagpur | Traffic Engineering | Module F

18

What we get here, we get here then μ_0 equal to $\alpha_0 \ln \frac{k_j}{k}$ by k by e . That means μ_0 equal to α_0 actually. So, now you simply substitute in equation 9.15. What was their μ equal to $\alpha_0 \ln \frac{k_j}{k}$ by k , but since α_0 equal to μ_0 . See you substitute that make it μ_0 what do you got eventually got Greenberg's macroscopic model.

$$\mu = \mu_0 \ln \frac{k_j}{k}$$

So, we started with third generation microscopic model as proposed by General Motors and with a simple with some simple steps and substitutions we could derive this Greenberg's macroscopic model; strong tie and this is really amazing and very important discovery. Because, looking at the traffic step you look at the microscopic with help on microscopic parameter look at with the help of macroscopic parameters, there is a connection. So, that was established.

(Refer Slide Time: 35:51)

GM Models & Macroscopic Traffic Flow Models

- Generalized form of GM model can be written as,

$$\ddot{x}_{n+1}(t + \Delta t) = \frac{\alpha_{l,m} [\dot{x}_{n+1}(t + \Delta t)]^m}{[x_n(t) - x_{n+1}(t)]^l} [\dot{x}_n(t) - \dot{x}_{n+1}(t)]$$
- Under steady state conditions GM models can give rise to different u-k models (macroscopic models)
- Figure shows different values of m, l would give rise to the macroscopic models

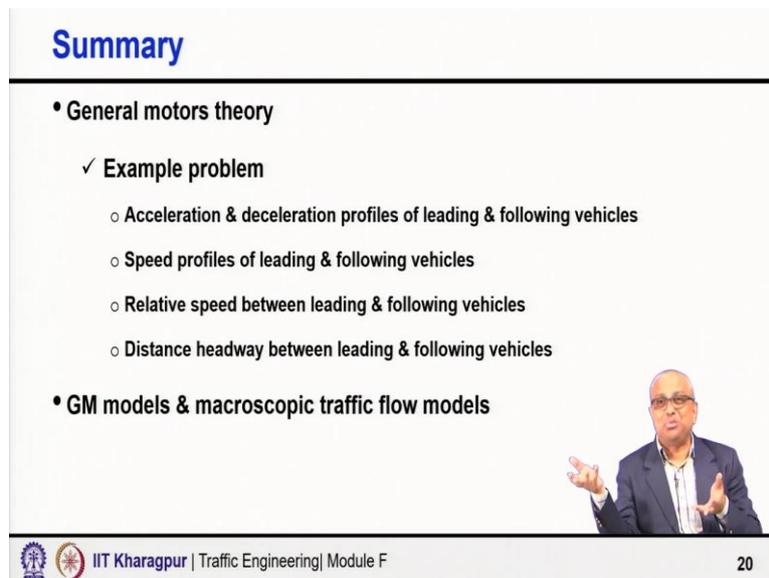

IIT Kharagpur | Traffic Engineering | Module F

19

In fact, the generalized GM model which can be written as I have shown it in terms of l and m actually I will stop here with this closing kind of statement. Actually, you can see and you can get with what value of l and m you are taking. Then it is possible that the GM model generalized model with specific different values of l and m can actually give you several microscopic model as I have shown you for some combination third generation models specifically it gives you Greenberg's model when l equal to 1 m equal to 0.

Similarly, with some other combination of n l m you can also get with m as 0 and l as 2 you can get actually the Greenshield's model, another combination can give you underwood's model. So, that shows the strength of the generalized model fifth generation generalized model as developed by General Motors that with different l and m, you can actually get several models established models which have been developed independently by researchers and which are all macroscopic models. So, there is a strong connection.

(Refer Slide Time: 37:37)

Summary

- **General motors theory**
 - ✓ **Example problem**
 - Acceleration & deceleration profiles of leading & following vehicles
 - Speed profiles of leading & following vehicles
 - Relative speed between leading & following vehicles
 - Distance headway between leading & following vehicles
- **GM models & macroscopic traffic flow models**

  IIT Kharagpur | Traffic Engineering | Module F 20

So, what we discussed? We discussed the General Motors theory in the previous lecture, we took an example problem to explain that and then also the other part the connection between generalized motors model the generalized fifth generation model GM model. Because all other models are specific cases of the generalized model fifth generation model first, second, third, fourth generation all at some specific cases of the fifth-generation model. So, generalized GM model General Motors model and the connection between that and the macroscopic traffic flow model. I explained only Greenberg, but you can get Greenshield you can also get other models from that. So, thank you so much.
