

## Second Level Algorithms

Prof. Palash Dey

Department of Computer Science and Engineering

Indian Institute of Technology, Kharagpur

Week – 04

Lecture 16

Welcome to the 16th lecture of the second-level algorithms course. In the last lecture, we have seen that the Ford-Fulkerson method works by studying the execution of that algorithm in a toy example, in particular, in the example where the greedy algorithm fails, and then we wrote an important lemma which will lead us to the proof of the Ford-Fulkerson method, the proof of correctness of the Ford-Fulkerson method. So, let us begin. So, the lemma basically says that given

a flow network  $G$  equal to  $(V, E)$ , and capacity values and a flow, if the following are equivalent. The first one is  $f$  is a maximum  $s$ - $t$  flow. The second one is  $G_f$  does not have any  $s$  to  $t$  path, and the third one is the value of  $f$  is the same

as the capacity of the  $s$ - $t$  cut  $(U, V \setminus U)$ , where  $U$  is the set of vertices reachable from  $s$  in  $G_f$ . So, clearly  $s$  belongs to  $U$  because  $s$  is reachable from  $s$ , and  $t$  does not belong to  $U$  because if there is no  $s$  to  $t$  path in  $G_f$ . So, we will show that these three conditions are equivalent. Let us first prove that 1 implies 2.

That means, assuming that  $f$  is a maximum  $st$ -flow, we need to show that there is no  $s$ -to- $t$  path in  $G_f$ . So, we will prove the contrapositive of this statement. That is, not 2 implies not 1. So, not 2 means there exists an  $s$ - $t$  path in  $G_f$ . So, assume that

there exists an  $s$ -to- $t$  path in  $G_f$ . Let us call this path  $P$ . Then we can augment the flow  $f$  using the path  $P$ , which, informally speaking, is the same as sending as much flow as you can along that path. to obtain another flow of value more than the value of  $f$ . Hence,  $f$  is not a maximum flow of  $G$ . So, we have proved 1 implies 2.

Now, let us prove 2 implies 3. That means we assume that there is no  $s$ - $t$  path in  $G_f$ , and we need to show that the flow value of  $f$  is the same as the capacity of a  $u$ - $v$  cut. So, we claim that for every edge  $u$ - $v$  in  $E$  with small  $u$  belonging to capital  $U$  (where capital  $U$  is

the set of vertices reachable from  $s$ ) and  $v \in V \setminus U$ , for every such edge  $u-v$ , the flow value  $f(u, v)$  must be the same as the capacity of the edge. Indeed, this must be the case; otherwise, if the flow value is strictly less than the capacity of the edge, then there will be a forward edge  $uv \in G_f$ . However, this implies that  $V$  is also reachable from  $s$  in  $G_f$ , right? So, pictorially, this is how it looks: this is  $V$ , this is  $U$ , this is  $s$ . Capital  $U$  is the set of vertices reachable from  $s$  in  $G_f$ .

Now, if the flow value of this edge is strictly less than the capacity of this edge, then the  $U$  to  $V$  edge is also present as a forward edge in  $G_f$ . Now,  $U$  is reachable from  $S$ , which means there exists a path from  $s$  to  $u$ , and because there is an edge from  $u$  to  $v$ , that means  $V$  is also reachable from  $S$ . But that contradicts our assumption that  $v$  belongs to  $V \setminus U$ . This contradicts our assumption that  $v \in V \setminus U$ . So, all the edges from  $U$  to  $V \setminus U$  the flow values should be the same as the capacity. We also claim that for every edge in  $E$  with  $x \in V \setminus U$  and  $y \in U$ , the flow value of such an edge must be 0. Pictorially, if this is  $V$  This is  $U$ ; here is the source node, here is the sink node, this is the residual graph, and this is the edge. So,  $y$  is reachable from  $S$ , and  $x$  is not reachable from  $S$ . Now, such edges must carry no flow. This must be the case; otherwise, there is a backward edge  $yx \in G_f$ .

If there is a positive flow from  $x$  to  $y$  edge, then by the definition of the residual graph, there will be a back edge from  $y$  to  $x$ . But again, this leads to a contradiction because  $y$  belongs to  $u$ , which means there is an  $s$  to  $y$  path. In  $G_f$ , and  $y$  to  $x$  is there in  $G_f$ . So,  $x$  must be in  $u$ , which contradicts our assumption that  $x$  belongs to  $V \setminus U$ . However, then since  $y$  belongs to  $u$ , and  $y$  comma  $x$ , this edge belongs to  $G_f$ ,  $y$  also must—sorry,  $x$  also must belong to  $u$ . This contradicts our assumption that  $x$  belongs to  $V \setminus U$ . So, all the edges from the  $u$  side to the  $V \setminus U$  side must carry the full amount of flow, and all the edges from the  $v$  side to the  $u$  side must carry no flow. Next, what we will show is that the flow value  $f$ , which is the sum of the flow values leaving  $s$ , must be the same as the sum of the flow values leaving  $u$ . In general, for any cut  $(U, V \setminus U)$ , the value of the flow  $f$  is the sum of the flow values leaving  $u$  minus the sum of the flow values entering  $u$ . But here, because all the incoming edges to  $u$  carry 0 units of flow, the sum of the flow values entering  $u$  is 0. So, this is so for this particular choice of  $u$ . Which is the set of vertices reachable from  $s$ , the value of  $s$  is actually the same as the sum of the flow values leaving  $u$ . So, to prove this, again consider the sum  $s$  equal to for every vertex  $u \in U$ , we sum up the total flow in  $U$  minus the total flow out of  $u$ . Now, let us see the value of this sum. So, the value of this if I look at from the vertex side, for every  $h \in U$  except  $s$ , this sum is 0.

So, this is the value of  $f$  since the sum is 0 for every vertex  $u$  in  $U$  except the source vertex.

On the other hand, if I look at it from each side, this is the sum of the flows leaving you minus the sum of the flows entering you. Considering the contribution of every edge in  $S$ ,  $S$  equals the total flow leaving  $U$  minus the total flow entering  $U$ . But as we have already seen, all the edges from  $V \setminus U$  to  $U$  carry 0 units of flow.

So, the total flow entering  $U$  is 0, and the total flow leaving  $U$ —we have already argued that all the edges going from  $U$  to  $V \setminus U$  carry the full amount of flow. So, this is the capacity of  $(U, V \setminus U)$ . So, what we got here is, on the one hand,  $S$  is the value of  $F$ ; on the other hand,  $S$  is the capacity of the S-T cut  $(U, V \setminus U)$ . So, this proves 2 implies 3. Now, we will show 3 implies 1. We assume that the value of  $f$  is the capacity of the s-t cut  $(U, V \setminus U)$ . We need to show that  $f$  is a maximum flow. So, let us take any maximum flow and show that the value of that maximum flow is the value of  $f$ . Let  $f'$  be any maximum S-T flow.

So, again repeating this analysis, that means considering the sum  $s$ , but instead of using  $f$ , using  $f'$ . What we get is that the value of  $f'$  is the capacity of  $(U, V \setminus U)$  minus because for  $f'$ , we cannot say that the total flow entering  $u$  is 0, because to argue this, we needed that the flow  $f_u$  is the set of vertices reachable in  $G_f$ . So, for any other flow  $f'$  for this set of vertices  $u$ , we cannot claim that this is 0.

So, we have—let us have this term—minus the total flow  $f'$  entering  $u$ . But we have assumed that the capacity of  $(U, V \setminus U)$  is the value of  $f$ . So, what we have is the value of  $f'$  is the value of  $f$  minus the total flow  $f'$  entering  $u$ , which is a non-negative number. So, this implies that the value of  $f'$  is less than or equal to the value of  $f$ . But  $f'$  is a maximum s-t flow. So, this implies that the value of  $f'$  is the same as the value of  $f$ .

So, this proves the lemma and thereby proves the correctness of the Ford-Fulkerson algorithm, except for one point: that it always terminates when all the capacities are rational numbers. So, let us stop here. Thank you.
