Lecture – 32
Detection
Theorem of Irrelevance & Waveform Detection

Good morning. Welcome to a new lecture in Detection. In this lecture we will basically talk about Theorem of Irrelevance and Waveform Detection. In last lecture what we did is, we took a simple case of binary antipodal PAM and we derived the bit error rate for binary antipodal PAM.

(Refer Slide Time: 00:45)

The image shows a hand-drawn equation on a grid background. The equation is $P_e = Q\left(\sqrt{\frac{2E_b}{N_0}}\right)$. Below the equation, there is a note "a, ||a||". In the bottom left corner, there is a small logo for NPTEL. In the bottom right corner, there is a small text "ETSC, IIT DELHI".

And we have seen that for binary antipodal PAM, the bit error rate is given by Q of square root of $2 E_b$ by N_{naught} where E_b is debate energy and n_{naught} denotes the one sided power spectral density of noise and then we started looking into vector detection. And we have said that for the case of vectors, everything remains same except that. Now instead of a , where a denotes the numerical value of the signal in binary antipodal PAM we have to work with norm of a ; that is it and there was other differences which we have looked into.

(Refer Slide Time: 01:40)

M-ary detection

m hypothesis

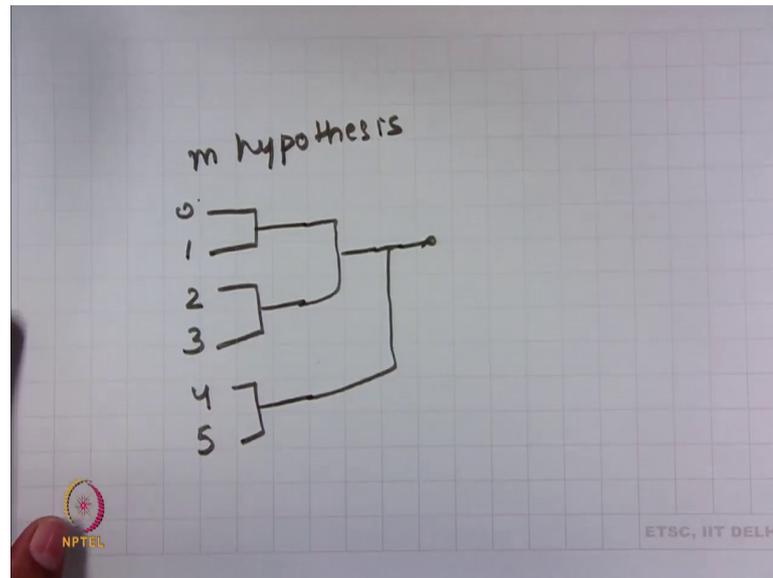

$$\Lambda_{m, m'}(v) = \frac{f_{v/H}(v/a_m)}{f_{v/H}(v/a_{m'})}$$
$$\Lambda_{m, m'}(v) \begin{cases} \geq \frac{P_H(m')}{P_H(m)} & H=m \\ < \frac{P_H(m')}{P_H(m)} & H=m' \end{cases}$$

Today we will start with first M-ary detection and in M-ary case we have m hypothesis, so m possibilities. And we can define the likelihood ratio in the same way as we have done previously. The only difference is, because there are m hypothesis now we need to have more number of likelihood ratios.

So, you can compare for example, m with m dash and let us say for the hypothesis m, if we transmit a signal a m and for hypothesis m dash we transmit a signal a m dash and so this likelihood ratio of m and m dash can be given by this. This was the ratio of likelihood when a m is transmitted divided by the likelihood when a m dash is transmitted. So, we get this likelihood ratio. And again if you have to decide on the hypothesis when comparing m and m dash, you need to see that if this likelihood ratio is greater than this threshold then we select the hypothesis as m; otherwise we select the hypothesis as m dash.

So, what we do in this a M-ary case, is we take two hypothesis at a time. We compare these two hypotheses and then we decide on one hypothesis which should be considered one later evaluations.

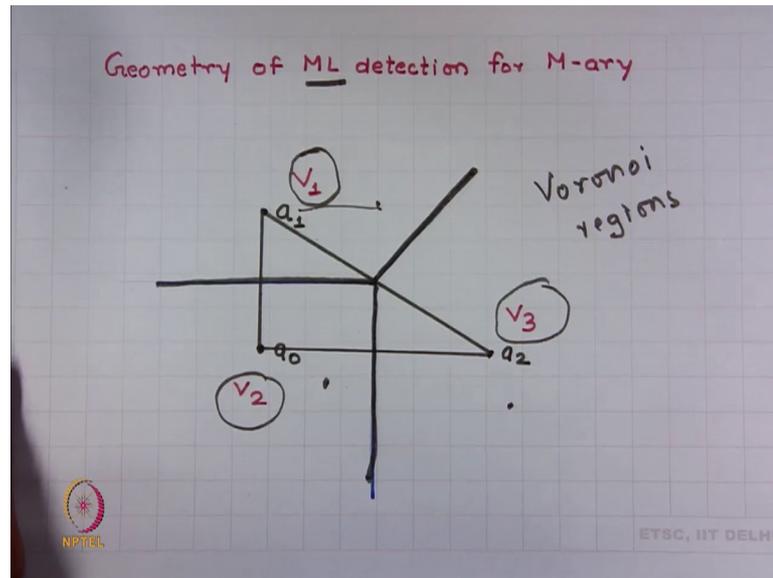

(Refer Slide Time: 03:04)

For example, if we have m hypothesis and we can consider 2 hypotheses at a time. For example, let us consider the case of 6 hypotheses, so we have to compare this with this, we decide on a winner, we compare this with this, we decide on a winner, we compare this with this, we decide on a winner and then we have to compare this with this decide on a winner and finally, you can compare this winner with this and finally, you can get the right hypothesis ok.

So, you can do decoding in this way. So, this is only difference in the case of M -ary, everything else remain same, likelihood ratios remain same, the likelihoods remain same, everything remains same, its just now you have to have more number of comparisons.

(Refer Slide Time: 04:05)

What is the geometry in the case of M-ary. So, in the case of M-ary as before we are focusing on the geometry in the case of maximum likelihood detector. So, in maximum likelihood we assume that the symbols are equiprobable. So, if we have this M L detector for M-ary you can find the Voronoi regions. So, Voronoi regions are the regions which are formed by drawing a perpendicular bisector between the 2 signals.

For example, if I consider signal a_1 and signal a_0 , these two points, I draw a perpendicular bisector between these signals. So, I get this perpendicular bisector, I can consider signal a_0 and a_2 , I get this perpendicular bisector. I can consider signal a_1 and a_2 and I get this perpendicular bisector ok.

So, I get now 3 Voronoi regions V_1 , V_2 and V_3 . So, Voronoi regions are the regions which are formed by drawing perpendicular bisectors between signals. And now the detection is simple, if the received symbol falls in this Voronoi region then I go with the hypothesis 1. If received signal falls in this Voronoi region then I go with hypothesis 0. If received signal falls in this Voronoi region then I go with the hypothesis 2.

So, in terms of geometry its pretty simple, you have various signal points, you draw perpendicular bisectors between the signal points and you get some Voronoi regions. And whenever a received signal lies in a Voronoi region you assume that this signal is corresponding to the hypothesis in, whose Voronoi region that signal is line. And again you can see here as well, this M L detector is simply calculating the distance of the

received signal from all possible signals and then it is deciding based on the minimum distance and this will become clear mathematically.

(Refer Slide Time: 06:36)

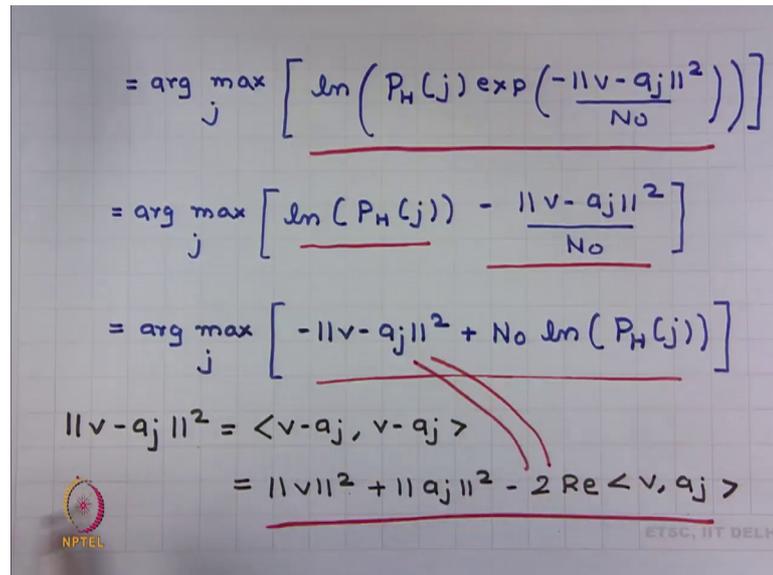

The image shows a handwritten derivation of the Maximum A Posteriori (MAP) rule. It starts with the title "MAP rule (revisited)" and the equation $H(v) = \arg \max_j (P_{H/V}(j/v))$, where $P_{H/V}(j/v)$ is labeled as "a posteriori". This is then expanded to $\arg \max_j (P_H(j) f_{V/H}(v/j))$, with $P_H(j)$ labeled as "a priori" and $f_{V/H}(v/j)$ labeled as "likelihood". Below this, it specifies "For Gaussian noise," and gives the final equation: $\arg \max_j (P_H(j) \frac{1}{\sqrt{\pi N_0}} \exp(-\frac{\|v - q_j\|^2}{N_0}))$. The slide also features a NITDEL logo in the bottom left and "ETSC, IIT DELHI" in the bottom right.

So, now I am really looking at this map detector again and by real looking at it I would derive some other ways in which you can think about this MAP rule. So, what was MAP rule , let us look at this. So, MAP says that I should choose the hypothesis as j and this hypothesis should maximize my a posteriori probability. So, this is a posterior probability. So, I should choose a hypothesis as the hypothesis which maximizes this a posterior probability. And we have also seen in the last lecture that this a posteriori probability maximization is same as maximizing this product. So, this is a priori probability and this is likelihood.

So, when we want to maximize this a posteriori probability, it is same thing as trying to maximize the product of a priori probability with likelihood. And for Gaussian noise, we also know what is this likelihood. So, I can simply substitute the probability density function of this random variable V given a hypothesis H is transmitted and let us assume that when hypothesis H is j , then the symbol value is a j

So, now we know that this is the probability density function of random variable V , given that hypothesis H is j . And what MAP detector would do, is it will try to find out j for which this quantity is maximum. And to simplify stuff I just take \ln here, natural log N here. So, when I try to maximize this quantity it is same as trying to maximize this.

(Refer Slide Time: 08:47)

$$\begin{aligned} &= \arg \max_j \left[\ln \left(P_H(j) \exp \left(-\frac{\|v - a_j\|^2}{N_0} \right) \right) \right] \\ &= \arg \max_j \left[\ln(P_H(j)) - \frac{\|v - a_j\|^2}{N_0} \right] \\ &= \arg \max_j \left[-\|v - a_j\|^2 + N_0 \ln(P_H(j)) \right] \\ \|v - a_j\|^2 &= \langle v - a_j, v - a_j \rangle \\ &= \|v\|^2 + \|a_j\|^2 - 2 \operatorname{Re} \langle v, a_j \rangle \end{aligned}$$

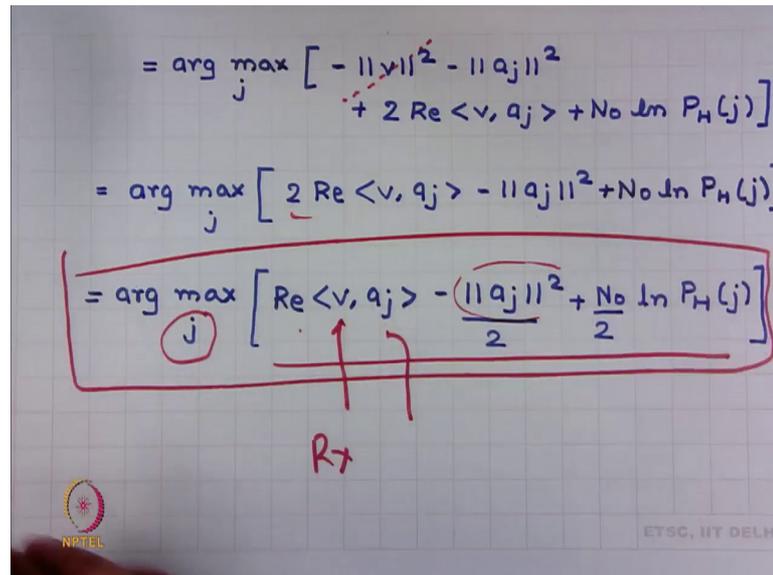

So, I am considering now this quantity with \ln here. Trying to maximize this thing is same as trying to maximize this thing ok, its having a natural log in here just simplifies this little bit. So, I know that log of a times b is simply log of a plus log of p. So, from this I get this. And then what I do is, I shift this N_0 to this side. So, from here I can simply get this. So, what is map detector doing, is it trying to find out j for which this quantity is maximum.

And then I use the property that norm of v minus a_j square can be simply calculated by finding the inner product of v minus a_j with v minus a_j . And we have solved this identity before and this is a good idea that you now memorize this that is norm square of v minus a_j is simply norm square of v plus norm square of a_j minus 2 times real part of inner product of v with a_j .

(Refer Slide Time: 10:09)

$$\begin{aligned} &= \arg \max_j \left[-\|v\|^2 - \|a_j\|^2 + 2 \operatorname{Re} \langle v, a_j \rangle + N_0 \ln P_H(j) \right] \\ &= \arg \max_j \left[2 \operatorname{Re} \langle v, a_j \rangle - \|a_j\|^2 + N_0 \ln P_H(j) \right] \\ &= \arg \max_j \left[\operatorname{Re} \langle v, a_j \rangle - \frac{\|a_j\|^2}{2} + \frac{N_0}{2} \ln P_H(j) \right] \end{aligned}$$

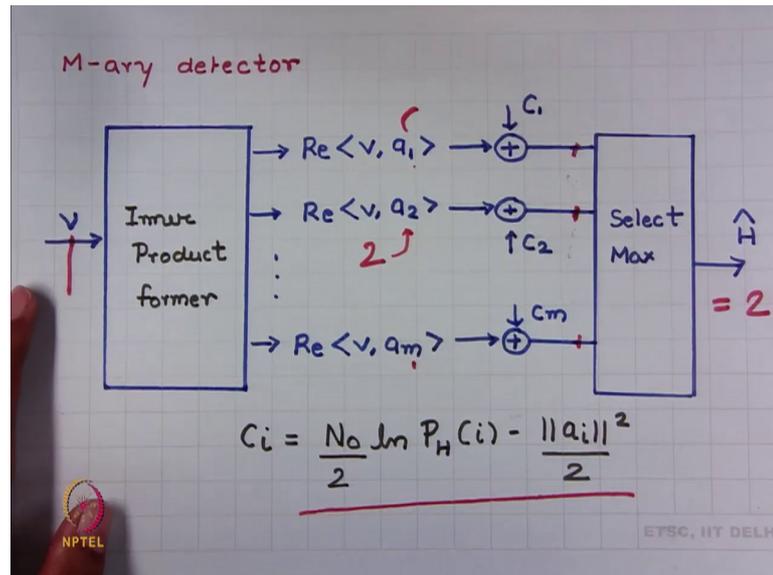

R_T

So, now substituting this thing in place of this, what I get is, that map detector should find the j for which this quantity is maximum. And as you can see that this is independent of hypothesis j , so, we can get rid of this, its not a function of j . So, I do not want to think about this, so what I have remained with is this. Now shifting two to these products I get this. So, now, what I get is that a map detector should find the hypothesis j for which this quantity is maximum and this is how you should design an M-ary detector.

So, first let us see what products we have. First we are having real part of inner product of v with a_j , v is the received vector, a_j is one of the possible transmitted vector. This corresponds to the energy of a_j by 2. And this terms deals with the probabilities of hypothesis; namely a priori probabilities of hypothesis. So, if you have to design an M-ary detector, you have to look at this equation. And based on this equation you can design an M-ary detector. For example like this.

(Refer Slide Time: 11:50)

So, what M-ary detector would be doing, is its taking a received vector, it will form the inner product of this received vector with signal set. So, it would take the inner product of v with a 1, where a 1 let us say corresponds to the signal corresponding to hypothesis 1 and so on and so forth. And then it takes the real part of this thing.

So, when it does it, it takes care of this term and to this it has to subtract or add this quantity. So, it adds C 1 where C i in general is this. And based on the outcome at this point it can decide for the possible transmitted hypothesis. A possible transmitted hypothesis is the one which has the maximum resultant here.

For example, if for the second hypothesis I am transmitting a signal a 2 and this branch has the highest outcome, then my predicted value of hypothesis will be 2. So, here I am assuming that I am having m hypothesis, where this corresponds to hypothesis 1, this corresponds to hypothesis 2, this corresponds to hypothesis m. And so m at a detector is a simple detector.

And this actually we have discussed way back in lecture 4, where we have said that detector is taking decision based on inner product of the received vector with the signal set and it adds some bias to this inner product and it takes the decision. And at the time I pointed out that we will figure out what is this bias when we have covered detection. It will be a very good idea that if you have this picture in mind; if you have this picture in mind then making detectors for digital communication system is trivial all right.

(Refer Slide Time: 14:11)

$$\begin{aligned} & \text{ML detector} \\ &= \arg \max_j \left[P_H(j) \exp\left(-\frac{\|v - a_j\|^2}{N_0}\right) \right] \\ &= \arg \max_j \left[\exp\left(-\frac{\|v - a_j\|^2}{N_0}\right) \right] \\ &= \arg \min_j \left[\|v - a_j\|^2 \right] \end{aligned}$$

Minimum distance decoding (MDD)

NPTEL ETSC, IIT DELHI

So, let us now move on to the case of M L detector. In the case of M L detector, I will be trying to maximize this quantity, but in case of M L detector these a priori probabilities are same for all hypotheses and thus we do not have to worry about this. M L detector simply tries to find out j for which this quantity is maximum. And trying to find out j for which this quantity is maximum is same thing as trying to find out j for which this quantity is minimum, because when this quantity is minimum, this quantity is going to be maximum.

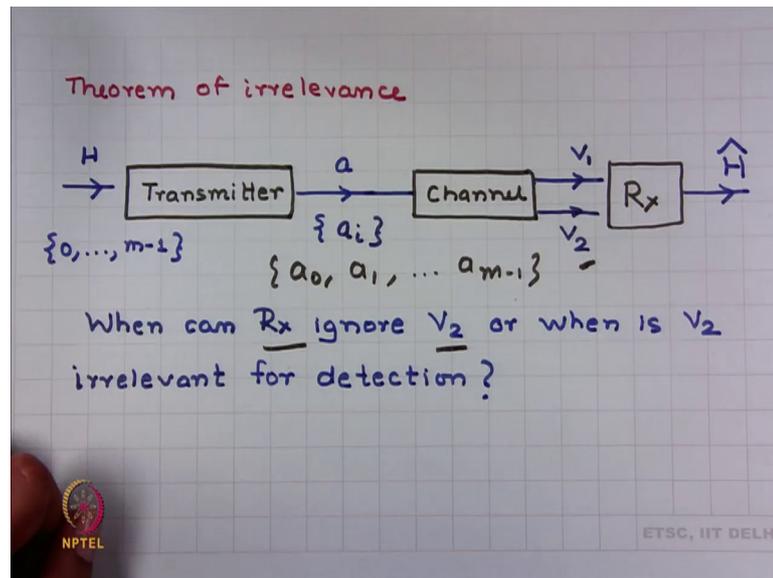

And what is this? This corresponds to the square of distance of the received vector with the symbol corresponding to the hypothesis. So, actually M L detector is simply trying to find out or to select the hypothesis which minimizes the distance from the received vector.

So, M L detector is also known as minimum distance decoder, because what is trying to do, is to find out the hypothesis for which the distance or the square of the distance is minimum. If the square of the distance is minimum the distance will also be minimum, and hence M L detector is also known as minimum distance decoder. We are done with vector detection.

So, in case of vector detection we have seen how to handle this complex vectors reception for the case of binary antipodal vectors. And also we have looked into the case of M-ary detection of vectors. And we have looked into the design of a map detector and

we have looked into the ideas behind M L detector and we have seen that M L detector is nothing, but it is simply a minimum distance decoder. Now, we have to go to this waveform detection and to go to waveform detection we have to look into what is known as theorem of irrelevance.

(Refer Slide Time: 16:29)

So, this will be useful theorem, if we try to understand how does the detector takes care of waveform. So, let us start, let us assume that I am having m hypothesis. Sometimes I choose hypothesis to go from 0 to m minus 1 and sometimes I choose the hypothesis to go from 1 to m , but it does not matter conceptually.

What it simply matters is that I have m hypothesis and corresponding to each hypothesis I am transmitting a signal, where signal belongs to a set; like for example, here to this set. So, I am having m quantized numbers. And whenever I try to transmit a hypothesis, I may transmit one of the numbers or one of the vectors, it does not matter dealing with numbers or dealing with vectors is not at all different.

Then I pass this through a channel and channel offers to this receiver two random variables; V_1 and V_2 . And based on looking at these two random variables, receiver has to predict the hypotheses. And the question that we are asking is, when can receiver ignore this V_2 or when is this V_2 irrelevant for detection. When receiver does not have to worry about this extra random variable V_2 , when can receiver simply decides optimally based on one received random variable; that is the question we are asking.

(Refer Slide Time: 18:27)

$$H(v) = \arg \max_j \left[P_H(j) f_{V_1/H}(v_1/j) f_{V_2|H,V_1}(v_2|j,v_1) \right]$$

$$\underline{f_{V_2|H,V_1} = f_{V_2|V_1}}$$

$$H(v) = \arg \max_j \left[P_H(j) f_{V_1/H}(v_1/j) \right]$$

So, let us look at the map case, what would be the a posteriori probability here. So, map rule remains same; that means, you are trying to find out the hypothesis for which this a posteriori probability is maximum. And this a posteriori probability is simply given by the a priori probability of hypothesis j to be transmitted, multiplied by the conditional probability density function of random variable V_1 taking in a numerical value small v_1 , given that hypothesis $H = j$.

So, multiply it by the conditional probability density function, that hypothesis H has taken a value j , random variable V_1 has taken a numerical value small v_1 . Conditioned on this event what is the PDF that random variable V_2 takes in a numerical value small V_2 . I can also write this in this way so that it is more clear.

(Refer Slide Time: 19:35)

$$f_{V_2 | H, V_1} (v_2 | j, v_1)$$
$$= f_{V_2 | H, V_1} (v_2 = v_2 | H=j, V_1=v_1)$$

So, this can be expanded like this. So, I am saying what is the PDF for which random variable V_2 take seed name numerical value V_2 , given that hypothesis is j and random variable V_1 has taken in a numerical value small v_1 .

So, when we have discussed about this random variables and random processes, we have said that we usually denote random variables with capital letters and numerical values of those random variables with small letters. So, this is the conditional PDF of V_2 given H and V_1 , all right. So, if this conditional probability density function of V_2 given H and V_1 does not depend upon the hypothesis; that means, this conditional PDF is same as the conditional PDF of V_2 given V_1 . Then what you can see is, this term will become independent of hypothesis and thus the choice of j does not influence this term. So, this term could be ignored.

Then in that case map rule simply reduces through this rule. So, map detector does not have to worry about this term, because this term will become independent of hypothesis, if the conditional PDF of V_2 given H and V_1 is simply conditional PDF of V_2 given V_1 , then this term will be independent of hypothesis and the map detector does not have to worry about this, because its constant with respect to j , its constant with respect to hypothesis does the map rule simply reduces to this. And thus if this condition is satisfied then V_2 becomes irrelevant for detector and that is what theorem of irrelevance says.

(Refer Slide Time: 21:53)

Theorem of irrelevance: An optimum Rx may disregard a vector V_2 if and only if

$$f_{V_2 | V_1, H} (V_2 = v_2 | V_1 = v_1, H=j)$$

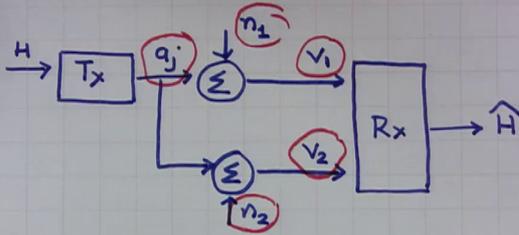

$$= f_{V_2 | V_1} (V_2 = v_2 | V_1 = v_1)$$

So, an optimum detector or receiver may disregard a vector V_2 , if and only if the conditional PDF of V_2 given V_1 and H is same as the conditional PDF of V_2 given V_1 ; that means, this was independent of H and then the receiver may disregard this vector V_2 and this is theorem of irrelevance. This theorem of irrelevance will help us to prove things precisely and that is why we are using it. So, to understand this theorem of irrelevance, let us look at 3 examples.

(Refer Slide Time: 22:32)

Ex:

$$v_2 = \underline{a_j} + \underline{n_2} \quad n_2 = v_2 - \underline{a_j}$$

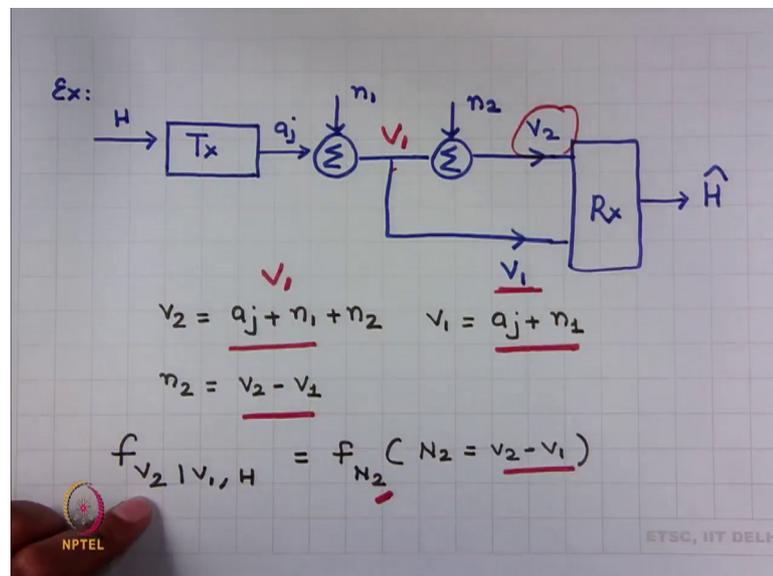

$$f_{V_2 | V_1, H} (v_2 | v_1, a_j) = f_{\underline{n_2}} (\underline{v_2 - a_j})$$

So, in this example I am transmitting hypothesis, this is the numerical value corresponding to this hypothesis, then noise sample n_1 adds to this transmitted symbol and I get a random variable V_1 . Here noise sample n_2 adds to this transmitted symbol and I get a random variable V_2 and the question is V_2 irrelevant for the receiver. And how do I think about this, what is this V_2 ? V_2 is a_j plus n_2 and what is this n_2 ? n_2 thus is V_2 minus a_j . Thus the conditional probability density of V_2 given V_1 and H , if this has been given to us is simply given by the PDF of the noise random variable, to take in a numerical value of n_2 .

And in that case numerical value of n_2 that it has to take is V_2 minus H . And hence conditional probability of V_2 given V_1 in h is a function of a_j , is a function of hypothesis and hence this V_2 is not irrelevant for receiver. And its quite obvious, because this V_2 is a function of a_j and is also a function of n_2 . So, by looking at this V_2 , your information might improve. For example, if I have a very noisy sample in here, and this sample is less noisy, then you have improved information about this transmit symbol if you look at V_2 . And hence we do is not irrelevant for receiver.

(Refer Slide Time: 24:38)

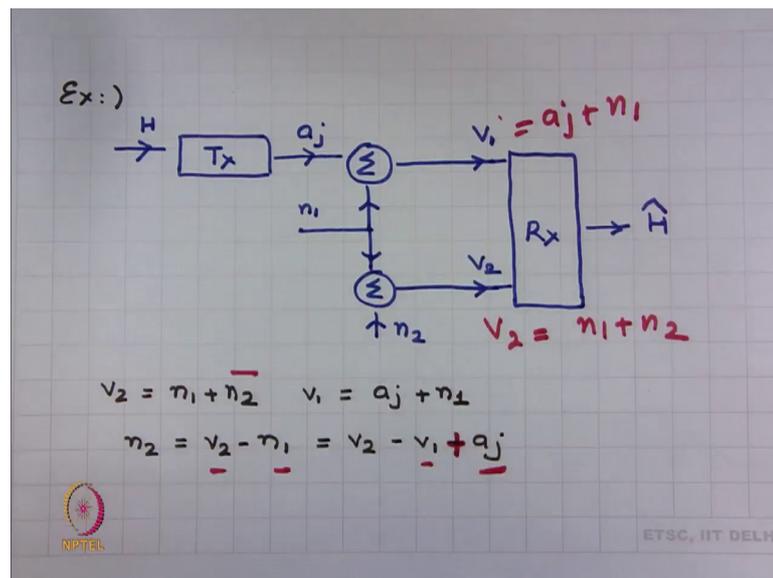

So, let us look at another case. So, here I am transmitting a_j , noise sample n_1 adds. So, this leads to random variable V_1 , V_2 is V_1 plus n_2 . So, V_2 is V_1 ; V_2 is V_1 , this is V_1 plus n_2 . And what is V_1 ? V_1 is a_j plus n_1 . So, if we look at n_2 , what is n_2 ? n_2 is

V_2 minus V_1 . And hence conditional PDF of V_2 given V_1 an edge, is simply conditional PDF of noise random variable, taking in a numerical value V_2 minus V_1 .

And this is not a function of hypothesis and hence this V_2 is irrelevant for receiver. So, this is a test that we have to do, where the channel is offering any useful information for the receiver. Our channel is offering a redundant information to the receiver

(Refer Slide Time: 25:57)

Let us look at the third case. Here I am having this V_1 as a_j plus n_1 . And this V_2 is n_1 plus n_2 . So, V_2 is n_1 plus n_2 , V_1 is a_j plus n_1 , what is n_2 ? n_2 from here is V_2 minus n_1 . And what is n_1 ? n_1 is V_1 minus a_j . So, this has to be plus anyways. So, n_2 is now a function of a_j and hence this random variable is not an irrelevant random variable, this is relevant.

Hence what is theorem of irrelevance is saying is, if you have to find out whether a random variable is irrelevant or relevant for the detector, you have to just see whether its conditional PDF is a function of hypothesis or not. If its not a function of hypothesis then this random variable is irrelevant for the receiver. Here in this case even though it looks that this random variable is not directly a function of hypothesis, but this will help us in learning about the noise n_1 . And this noise n_1 is also present here.

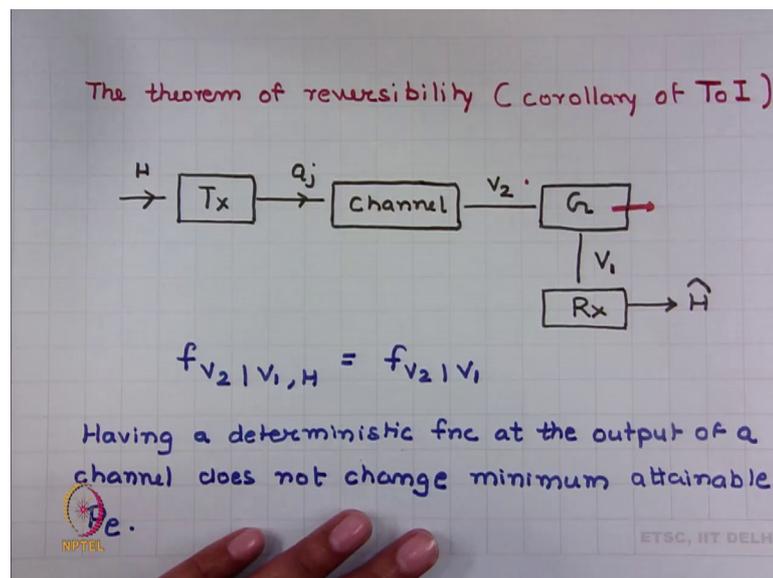

And thus intuitively you may feel that because by looking at this random variable I can learn about this n_1 , because this V_2 is n_1 plus n_2 . And this V_1 also has n_1 so, I have

a better chance of trying to find out about the hypothesis. So, intuitively also you can understand about these things.

Let us look at the other examples, whether intuitively can we find about these things. So, V_2 in this case is simply V_1 plus n ; that means, V_2 is a noisy version of V_1 . If V_1 is already present and if V_2 is just noise plus V_1 , then you are not helping in learning about V_1 at all and hence this is an irrelevant statistic. If I look at the first example, here this hypothesis is present in both V_1 and V_2 . And as I have said it is possible that for example, here the noise amplitudes might be very small and because you are having hypotheses in both branches this is of course, not an irrelevant statistic.

So, what idea I am trying to convey is sometimes you can work this out through maths as we have done and sometimes also you can intuitively think whether random variable is relevant or irrelevant for the detector.

(Refer Slide Time: 29:05)

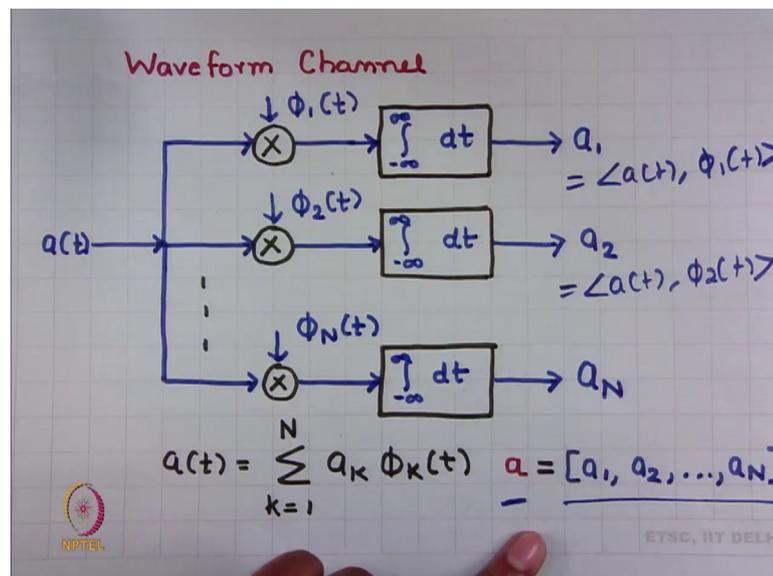

There is corollary of theorem of irrelevance and that goes by the name of theorem of reversibility. This theorem says that if at the output of a channel you are having a deterministic function. For example, this g is a deterministic function. Now the conditional PDF of V_2 given V_1 and hypothesis, is simply conditional PDF of V_2 given V_1 , because this is a deterministic function. As soon as you are given this V_2 , you know V_1 is not it.

And this transformation, because its a deterministic function does not at all depend upon hypothesis and hence whether you observe V_1 or you observe V_2 you get the same probability of error. Probability of error does not change by introducing any deterministic function at the output of a channel.

So, sometimes you might be given a very complicated deterministic function. And if you have to worry about what is the probability of error of this receiver, you can simply estimate the probability of error at this point and you will get the same probability of error. So, that is clear from this theorem of reversibility. Now after having understood this theorem of irrelevance, now we can safely move to this waveform channel, because we will require this theorem of irrelevance to understand this waveform channel ok.

(Refer Slide Time: 30: 42)

So, here we are having this waveform channel and this picture we have seen before as well, I am trying to revise these things. So, when we have talked about signal spaces, we have several times have shown this picture. So, we have a deterministic signal $a(t)$ built using different orthonormal function. So, $a(t)$ is built using different orthonormal functions or its a weighted sum of different orthonormal functions.

And though this equation looks very naive and simple, but I guarantee you that you can think about any modulation scheme, whatsoever it is, in terms of this equation. So, any modulation scheme, whether its PAM COM FSK, PPM, CDMA whatsoever it is, can be thought in terms of this basic equation. So, this equation holds for both linear

modulation, non-linear modulation. Whatever it may be the kind of modulation scheme you can convert any modulation scheme to this simple basic equation, and thus this equation is very generic.

So, you can think about any modulation scheme. Any modulation scheme creates a signal as a weighted sum of orthonormal functions. In PAM there is only basic orthonormal function and all other orthonormal functions are time shifted version of the same basic orthonormal function. In com you have two basic orthonormal functions. In FSK, in M-ary FSK you have m orthonormal functions. So, whatever is the modulation scheme, all these modulation schemes can be thought in terms of this basic equation.

So, any waveform, you can pass through various correlators. So, we know that this is a correlator tuned to this $\phi_1(t)$. So, this correlator will extract the component of $a(t)$ along this $\phi_1(t)$. So, a_1 as we have seen is nothing, but is the inner product of $a(t)$ with $\phi_1(t)$. a_2 is inner product of $a(t)$ with $\phi_2(t)$ and so on so forth.

So, basically what you can get is corresponding to this $a(t)$ you can have these coefficients; a_1 a_2 up to a_N . And the collection of this element we are saying as a vector \mathbf{a} . So, up to now we have been thinking about what happens to this vector \mathbf{a} , we have understood clearly the vector reception; that is \mathbf{a} . So, vector \mathbf{a} is the collection of some coefficients; a_1 a_2 and a_N .

So, a case are the coefficients of this vector \mathbf{a} . So, when I have a waveform I pass it through a bunch of correlators, I get to the vector corresponding to this waveform. And I can generate this waveform also like this by multiplying these various orthonormal functions with these coefficients and these are the elements of that vector \mathbf{a} . And what I have said is you can think about any modulation scheme using the simple basic idea, any waveform is weighted sum of orthonormal functions all right.

So, here my receiver would be receiving $a(t)$ and it would be giving me a vector corresponding to this $a(t)$, because I know how to handle this vector, I know how to detect this vector. So, once I have this vector then it looks like my problem is half solved. And only thing that now I have to prove is that when I go from this step to this step, I do not lose out on information ok or nothing bad happens that I cannot hand it.

(Refer Slide Time: 34:47)

$$V(t) = a(t) + N_w(t)$$

$N_w(t)$: Additive White Gaussian Noise

Additive \Rightarrow Independent of signal

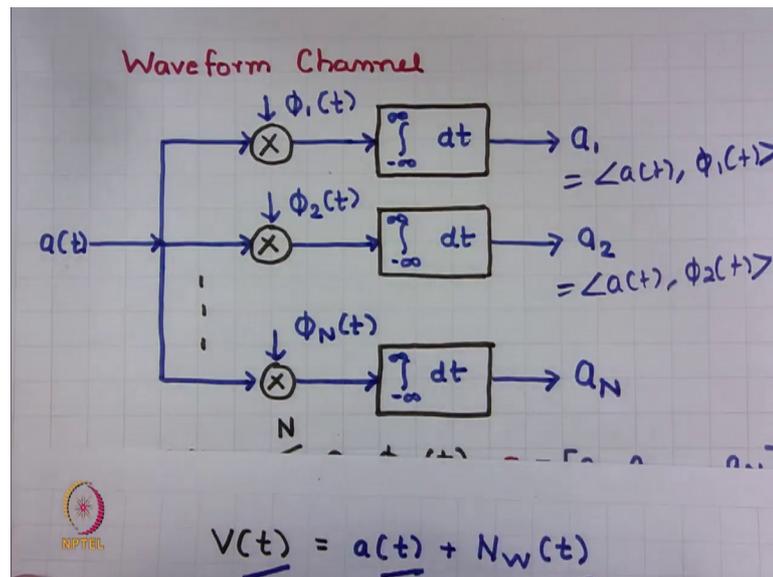

$$V_j \triangleq \int_{-\infty}^{\infty} V(t) \phi_j(t) dt$$

$V \triangleq [V_1, V_2, \dots, V_N]$

So, at the receiver I am receiving a waveform which is a t the transmitted one plus noise; that is what we have said we are assuming AWGN channel. So, noise adds to the signal, the underlying noise is assumed to be white Gaussian. So, $N_w(t)$ is nothing, but it is additive white Gaussian noise. And we have also said sometime back that additive means that it is independent of signal.

Let us see what happens if this random process, this is a random process, because this is a random process. So, $V(t)$ is a random process and hence we are using this capital letter V of t , whereas this is a deterministic function and hence we are using a small letter a alright. So, I am having a random process $V(t)$, I am passing this random process through those bunch of orthonormal functions that I have. And I extract an element of vector in the same way as I was extracting the element of the vector a .

(Refer Slide Time: 35:47)

So, I pass this random process through a deterministic function. I already know what is this? This is a linear functional of the random process a linear functional of the random process, is a random variable. So, I am getting the random variable, corresponding to this orthonormal function $\phi_j(t)$ and hence I am using a subscript j .

Similarly, I can get random variables corresponding to each orthonormal function and I can construct as a random vector. So, this is a Gaussian random vector. So, vectors in this lecture I am denoting using red color, because I am having variables and vectors at the same time. So, I thought it is a good idea to use a different color for vectors. So, I am using red color for vectors ok.

So, random vector V , is simply the collection of n random variables and these random variables are obtained by the projection of this random process along these orthonormal functions that I am using to generate signal set, generate or to receive both ways, it cuts both ways all right.

So, I have said that I am having a Gaussian random vector which I form by collecting random variables which are obtained by passing this random process through various orthonormal functions.

(Refer Slide Time: 37:27)

$$\begin{aligned} V_j &\triangleq \int_{-\infty}^{\infty} v(t) \phi_j(t) dt \\ &= \int_{-\infty}^{\infty} (a(t) + N_w(t)) \phi_j(t) dt \\ &= \int_{-\infty}^{\infty} a(t) \phi_j(t) dt + \\ &\quad \int_{-\infty}^{\infty} N_w(t) \phi_j(t) dt \end{aligned}$$

So, I am saying one random variable V_j is simply obtained by projection of this random process along one orthonormal function. And I know what is this V of t ? V of t is nothing, but a t plus discussion noise and I can break this down into 2 components; this plus the projection of white Gaussian noise on these orthonormal functions.

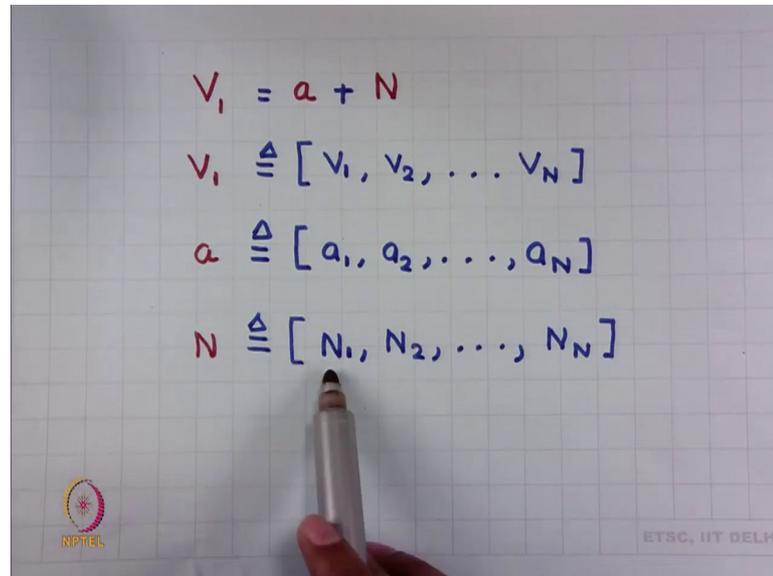

(Refer Slide Time: 37:58)

$$\begin{aligned} a_j &\triangleq \int_{-\infty}^{\infty} a(t) \phi_j(t) dt \\ N_j &\triangleq \int_{-\infty}^{\infty} N_w(t) \phi_j(t) dt \\ V_j &= a_j + N_j \end{aligned}$$

And I have already defined a_j are the coefficients of projections of $a(t)$ on this $\phi_j(t)$, and I can define n_j as the coefficients of projections of this white noise on this $\phi_j(t)$. Once I choose this definition my V_j is simply a_j plus N_j , where N_j is the projection of

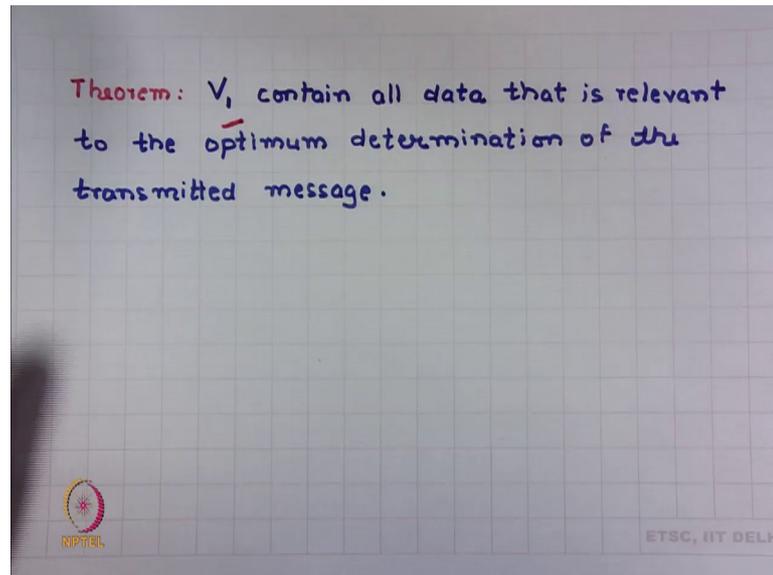

white noise on these orthonormal functions, a_j corresponds to the projection of signal on these orthonormal functions and V_j is sum of these two coefficients ok. Its a random variable because N_j is a random variable.

(Refer Slide Time: 38:40)

$$V_j = a_j + N_j$$
$$V_j \triangleq [v_1, v_2, \dots, v_N]$$
$$a \triangleq [a_1, a_2, \dots, a_N]$$
$$N \triangleq [N_1, N_2, \dots, N_N]$$

Now, if you know this then you can also know that random vector V is simply a sum of 2 vectors a and N . Where the elements of a are the coefficients of projections of signal on orthonormal functions and the coefficients of N are the projections of white Gaussian noise on these orthonormal functions. So, what I am doing is, simply translating this. So, this relates that the coefficients of this random vector V is sum of coefficient of vector a plus coefficient of random vector N . If V_j is a_j plus N_j then we know that V is also a plus N all right.

(Refer Slide Time: 39:37)

Why we are doing this, because we are trying to worry about stating and proving a theorem that V_1 contain all data that is relevant to the optimum determination of the transmitted message and this is a deep statement. Because it says that this random vector V_1 is sufficient and optimum for the detection of the transmitted message and this is what we are going to prove.

(Refer Slide Time: 40:17)

$$V_1(t) \triangleq \sum_{k=1}^N v_k \phi_k(t) = \underbrace{a(t)}_{(a_k + N_k)} + \underbrace{N(t)}$$
$$a(t) = \sum_{k=1}^N a_k \phi_k(t)$$
$$N(t) \triangleq \sum_{k=1}^N N_k \phi_k(t)$$

The image shows handwritten equations on a grid background. A hand is visible on the left side of the page. The equations are written in blue ink. In the first equation, the term $a(t)$ is underlined and has a red bracket underneath it with the label $(a_k + N_k)$. In the third equation, the term N_k is circled in red with an arrow pointing to it from below. In the bottom left corner, there is a logo for NPTEL. In the bottom right corner, there is a logo for ETSC, IIT DELHI.

So, $V_1(t)$, as I have said is simply a weighted sum of these orthonormal functions and the weights are decided by these random variables V_k . And these random variables V_k is

simply $a(t) + N(t)$. And we know that this is $a(t)$ and this is $N(t)$, so you can also say that $V(t)$ is simply $a(t) + N(t)$. It is the deterministic signal and $N(t)$ is the white Gaussian noise projected on orthonormal functions.

So, we project white Gaussian noise on orthonormal functions, you get these random variables and you form weighted sum of these orthonormal function, using these random variables you get a random process and this random process is referred to as $N(t)$.

(Refer Slide Time: 41:17)

$$\begin{aligned}
 \underline{V(t)} &= \underline{V_1(t)} + \underline{V_2(t)} \\
 \underline{V_2(t)} &\triangleq \underline{V(t)} - \underline{V_1(t)} \\
 &= \underline{a(t)} + \underline{N_w(t)} - \underline{a(t)} - \underline{N(t)} \\
 V_2(t) &= N_w(t) - N(t)
 \end{aligned}$$

So, this is $V(t)$ which is $a(t) + N(t)$; $V(t)$ is the total signal that was incident on the receiver. And this total signal we say is sum of $V_1(t)$ plus $V_2(t)$, where I define this $V_2(t)$ as $V(t)$ minus $V_1(t)$, so obvious. And what is this $V(t)$? $V(t)$ is $a(t)$ plus white Gaussian noise, its complete white Gaussian noise, its unprojected white Gaussian noise, it its a noise that lies in infinite dimension minus $V_1(t)$ and $V_1(t)$ is as I have said $a(t) + N(t)$, $N(t)$ is a finite dimensional noise. Its a noise that is lying only on the signal space. What is a signal space? Signal space is formed by those bunch of correlators.

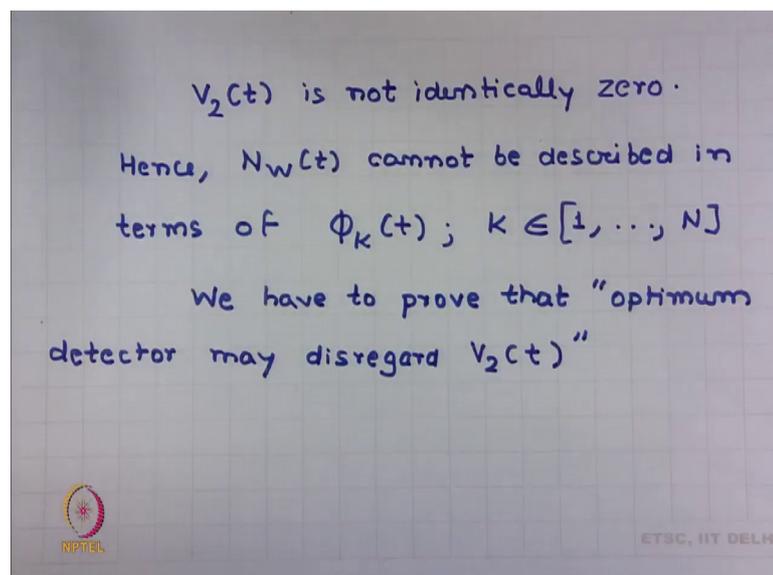

So, if signal is expressed over N orthonormal functions, these N orthonormal functions are deciding that signal space. $N(t)$ is the projection of white Gaussian noise on that signal space and $w(t)$ is the total white Gaussian noise. This white Gaussian noise runs over infinite dimension. And hence $V_2(t)$ is simply this infinite dimensional noise minus the noise that is projected and the signal space. And what we are saying is, this $V_1(t)$ is only sufficient for the receiver and this $V_2(t)$ is actually irrelevant for the detection, we do not

care about this $V_2(t)$. And thus when this noise is projected only over finite number of dimension we do not lose anything on optimality, that is an argument we are trying to put forward.

So, let me restate the argument, because its kind of an important and tricky argument to understand. What we are seeing is, at the input of the receiver, we were having a signal plus infinite dimensional white Gaussian noise. Now when this signal and infinite dimensional white Gaussian noise is projected on these finite orthonormal functions. At the output of those finite orthonormal functions I am getting the signal completely plus finite dimensional noise.

And there is certain noise that is lost out in that process. I am saying that that noise, which disappeared, is actually $V_2(t)$ and that disappeared noise is not relevant for our receiver. That noise will not improve our understanding about the hypothesis and this is what we are going to prove. $V_2(t)$ will not be identically zero and because a white Gaussian noise cannot be described in terms of finite dimensions, $\phi_k(t)$ is a finite dimensional space, because k is a finite number. It will go from 1 to N or from zero to N minus 1 and this is what we have to prove that optimum detector may disregard this $V_2(t)$.

(Refer Slide Time: 44:09)

And once $V_2(t)$ can be safely disregarded, we can safely say that when you convert these waveforms to vectors you are not losing out on optimality right. Whatever is lost out is

not relevant for the detection. What is relevant for the detection is, the vectors that you have obtained and the output of the correlator; that is it right.

(Refer Slide Time: 45:05)

The image shows a whiteboard with handwritten mathematical expressions. At the top, a vector V_2 is defined as $V_2 = [v_2(t_1), v_2(t_2), \dots, v_2(t_q)]$. Below this, the conditional PDF $f_{V_2|V_1, H}$ is equated to $f_{V_2|N, H}$. To the right, V_1 is defined as $V_1 = a + N$. The general formula for conditional PDF is given as $f_{X/Y}(x/y) = \frac{f_{X,Y}(x,y)}{f_Y(y)}$. Finally, the specific case is shown as $f_{V_2|N, H} = \frac{f_{V_2, N, H}}{f_{N, H}}$. A red arrow points from the general formula to the specific case.

Let us see the proof. So, V_2 we are forming a random vector, red color tells us about the vector, as a collection of various random variables and I obtain these random variables by sampling the process $V_2(t)$ at various time instances. So, we have seen that if you have a random process, you sample this random process at various time instances you get random variables and this random vector is nothing, but its a collection of random variables. So, what we have to prove is, the conditional PDF of V_2 given V_1 in H is simply independent of hypothesis; that is it and then we know that this V_2 is irrelevant for deduction from theorem of irrelevance.

Let us see what is this conditional PDF of V_2 given V_1 and H , is same as the conditional PDF of V_2 given that N has taken some particular values. For example, what is this V_1 ? Let us say its a plus N . So, if I want to find probability density function of V_1 . This is same as the probability density function of this random variable taking the numerical values N , because this is a deterministic function.

So, that is what we are saying. So, the conditional PDF of V_2 given V_1 and H , is simply conditional PDF of V_2 given N and H . And from one of the lectures on this conditional PDF we know that, the conditional PDF of X given Y is simply the joint PDF of X and Y divided by the PDF of Y . We are losing out on arguments, because this is not central here

ok. I could have written this as, this as well does not matter. So, I am losing out on the arguments, just to keep things concise, but you know how you have to fail in this.

So, we know that the conditional PDF of X given Y is joint PDF of X and Y divided by PDF of Y and thus conditional PDF of V_2 given N and H is joint PDF of V_2 N and H divided by joint PDF of N and H. Using this property we can get to this.

(Refer Slide Time: 47:51)

$$\begin{aligned}
 \underline{f_{V_2|N,H}} &= \frac{f_{V_2,N,H}}{f_{N,H}} \\
 &= \frac{f_{V_2,N} f_H}{f_N f_H} \\
 &= \frac{f_{V_2,N}}{f_N} = f_{V_2}
 \end{aligned}$$

So, from this conditional PDF of V_2 given N and H, we have already said that this is the case. And this hypothesis is independent of noise and as well as on V_2 , because this is a residual noise. So, hypothesis H is independent of both V_2 N H and thus the joint PDF is simply the multiplication of these PDFs. So, joint PDF of V_2 N and H, is simply the joint PDF of V_2 and N multiplied by marginal PDF of H.

And because H is again independent of N, signal is independent of noise, because its additive white Gaussian noise. So, this I can write as multiplication of these two PDF, and from here I can cancel this with this. So, from this what we can get is that this, is simply joint PDF of V_2 and N divided by PDF of N.

And now what remains is to identify that this N is also independent of this V_2 . And then you can easily prove that this is nothing, but PDF of V_2 . So, V_2 does not depend upon N, it does not depend upon hypothesis. That means, if you observe this V_2 , neither you can learn about N noise, nor you can learn about hypothesis, you cannot learn about

anything. And once you are neither learning about noise that is present in that signal space. If you are not learning about the hypothesis then of course, its a irrelevant statistic.

(Refer Slide Time: 49:54)

$$\begin{aligned}
 & \text{Cov} (\underline{v_2(t)}, \underline{N_k}) \\
 &= E [\underline{v_2(t)} \underline{N_k}] \\
 &= E [(N_w(t) - N(t)) \underline{N_k}] \\
 &= E [\underline{N_w(t)} \underline{N_k}] - E [\underline{N(t)} \underline{N_k}] \\
 &= \frac{N_0}{2} \underline{\phi_k(t)} - \frac{N_0}{2} \underline{\phi_k(t)} \\
 &= 0
 \end{aligned}$$

So, what we have to prove is this n is also independent of this V_2 . So, to do that let us look at this covariance of $V_2 t$ with this N case and because both are zero mean. I can simply think about this covariance as expected value of $V_2 t$ times N_k , then I can expand on this $V_2 t$. $V_2 t$ is nothing, but this total white Gaussian noise minus the white Gaussian noise present in the finite dimension and we know what is N_k . So, from here I can get to these two expectation.

And we can prove that this is nothing, but this and this is also same as this. And from here I can get the covariance is zero. And if covariance is zero; that means, $V_2 t$ is uncorrelated with N_k . And if this $V_2 t$ and N case are uncorrelated, we know that they are also statistically independent and this will prove that N_k s are statistically independent of these V_2 ts.

(Refer Slide Time: 51:12)

$$\begin{aligned}
 \underline{f_{V_2|N,H}} &= \frac{f_{V_2, N, H}}{f_{N, H}} \\
 &= \frac{f_{V_2, N} \cancel{f_H}}{f_N \cancel{f_H}} \\
 &= \frac{f_{V_2, N}}{f_N} = f_{V_2}
 \end{aligned}$$

And thus this will simply reduce to probability density of V_2 . And thus looking at V_2 will not improve your knowledge about hypothesis. So, we have very quickly gone to this step to this step and from here to here, let us prove this as well all right.

(Refer Slide Time: 51:37)

$$\begin{aligned}
 E[N_w(t) N_k] &= \\
 E[N_w(t) \int N_w''(s) \phi_k(s) ds] &= \\
 = \int E[N_w(t) N_w(s)] \phi_k(s) ds &= \\
 = \frac{N_0}{2} \int \delta(t-s) \phi_k(s) ds &= \frac{N_0}{2} \phi_k(t) \int \delta(t-s) ds \\
 = \frac{N_0}{2} \phi_k(t) &
 \end{aligned}$$

So, let us prove, what is expected value of $N_w(t)$ times N_k . N_k I can write like this, because N_k is our the projection of this white Gaussian noise on these orthonormal functions. I can interchange this expectation and integration operation, pulling integration through this side, getting an expectation. Here we have done several such

examples while running through week 3 4 and 5. So, I am doing this variant first, because we have already done several such operations. In fact, we have also solved this before ok, just revising and that is why we are doing it a little bit quickly.

So, we get expected value of this. And we know what is expected value of this thing, because it's a white Gaussian noise, its power spectral density is $N_0/2$ and it's uncorrelated. And thus we can demonstrate this through an impulse function. So, if t is different from s then you should get a flat 0, because any two samples of a white Gaussian noise are uncorrelated right. So, you can only get an expectation when s is same as t ; otherwise you get a flat 0 and this effect is created by having an impulse at t minus s , because if s is not t then you get flat 0. If as the same as t then you get $N_0/2$ which corresponds to the power spectral density of the noise.

So, this is a $N_0/2$ times integration of this thing. And this creates an effect that this s has to be t otherwise this is going to be 0. So, s is t , this is $\phi_k(t)$. $\phi_k(t)$ is not a function of s , it could be pulled out. So, this becomes $N_0/2 \phi_k(t) \int \delta(t-s) ds$ and this is one, integration of an impulse is one, so we get this. So, there complete the first proof that expected value of $N(t) \times N(k)$ is this thing. Now, let us check on this, what is this.

(Refer Slide Time: 54:02)

$$\begin{aligned}
 & E[N(t) N(k)] \\
 &= E\left[\sum_{j=1}^N N_j \phi_j(t) N(k) \right] \\
 &= \frac{N_0}{2} \phi_k(t)
 \end{aligned}$$

The derivation shows the expectation of the product of two noise samples. The first step is $E[N(t) N(k)]$. The second step is $E\left[\sum_{j=1}^N N_j \phi_j(t) N(k) \right]$. A red bracket is drawn under the sum, and a red arrow points to the result $= E[N_k^2] \phi_k(t)$. The final result is $= \frac{N_0}{2} \phi_k(t)$. A hand is visible at the bottom left of the slide, and there is an NPTEL logo in the bottom left corner.

So, we have to worry about what is expected value of $N(t)$ times $N(k)$. $N(t)$ know I am writing in terms of orthonormal functions. Again these random variables will be

uncorrelated and their expectation would be zero, except when j is same as k . So, multiplying N_k with all other terms will make it flat 0 and hence in the summation there is only N_k that we have to worry about. So, in that case this will be expected value of N_k square times $\phi_k t$. An expected value of N_k square is N naught by 2. And hence this proof is completed.

So, now you can believe me that the covariance of these two quantities is 0. Hence these two things are statistically independent. Once these are statistically independent this is same as this. So, you can write the joint PDF in terms multiplication of marginal PDFs and this cancels with this and you get conditional PDF of V_2 given N and H is simply PDF of V_2 .

(Refer Slide Time: 55:03)

$V_2(t)$ is statistically independent of N_k

$$f_{V_2 | N, H} = \frac{f_{V_2, N}}{f_N} = \frac{f_{V_2} f_N}{f_N} = \underline{f_{V_2}}$$

So, with this we have proven that in the case of waveforms, we pass this waveform through orthonormal functions, you get the signal plus the projection of infinite dimensional white Gaussian noise on the signal space and you get bunch of vectors. You get a vector corresponding to a signal; you get a vector which is obtained by the projection of that infinite dimensional white Gaussian noise onto the signal space. You add these two things up and you get a vector which we call as V_1 and we are saying that this vector V_1 is optimal for the receiver.

Whatever noise is left out is not required for detection, its irrelevant for detection, because that noise is the statistically independent of the noise present in the signal space,

and its also statistically independent of hypothesis. And thus by looking at that noise you would not learn anything, either about the noise present in the signal space or about the hypothesis. And hence when we go from waveform to, vectors we lose out something, but whatever we lose out its not important for detection.

And hence when we are defining the optimum rule for waveform detectors, these rules are exactly same as the rules that we developed of a vectors. And this we will complete in the next lecture, where we will see that there is complete equivalence between the rules for waveform detection and the rules for vector detection ok. So, with this we will move into next lecture.

Thank you.
