Lecture - 03
Energy/ Power Signals, Unit Impulse Function, Complex Exponential

Hello. Welcome to another module in this massive open online course. So, let us continue our discussion on the classification of signals let us look at energy and power signals ok.

(Refer Slide Time: 00:24)

SIGNALS

$$E = \int_{-\infty}^{\infty} |x(t)|^2 dt$$

Energy of Signal.

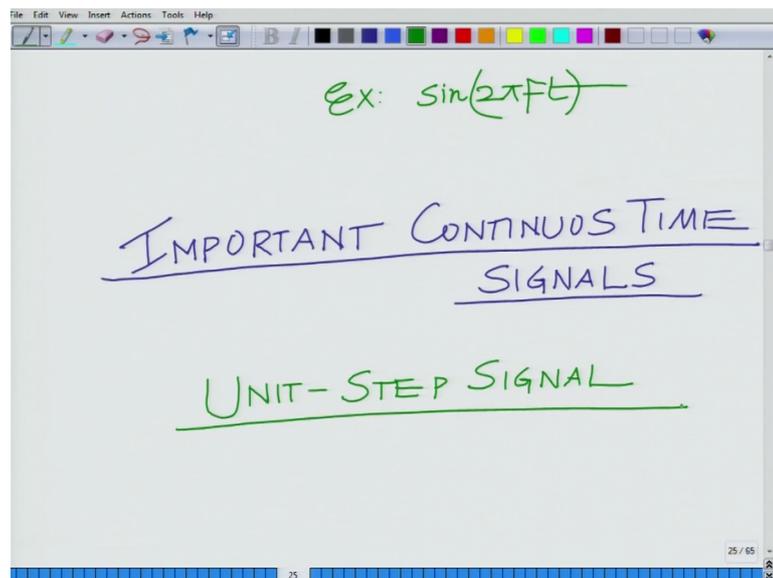

$$E = \sum_{n=-\infty}^{\infty} |x(n)|^2$$

So, what we want to look at is the concept of energy and power signals and the energy of a signal is defined energy of a signal $x(t)$ continuous signal $x(t)$ is defined as well minus infinity to infinity magnitude $x(t)$ square dt . This is the definition of an energy of the signal and the energy of a discrete time signal is well summation n equal to minus infinity to infinity magnitude $x(n)$ square. This is the energy of a discrete time signal and a signal is an energy signal.

power of minus n u of n this is a this is a these are energy signals that is signals whose energy energies are finite ok.

And we also have the notion of power signals that is the power let us first define the power p of a signal equals well this equals limit t tending to infinity minus t over 2 to t over 2 one by t that is dividing by t magnitude x t square dt and the same thing can be defined for digital signal that is limit n tending to infinity one over a discrete time signal one over 2 n plus one summation n equals or summation n equals minus n 2 plus n magnitude of magnitude of x_n square. This is the power of a discrete time signal and if the power is finite if the power of the signal that is continuous time signal or discrete time signal is finite then it is known as a power signal. So, if that is 0 less than p less than infinity this implies; it is a power signal. So, this implies it is a power signal and a classic example of a power signal.

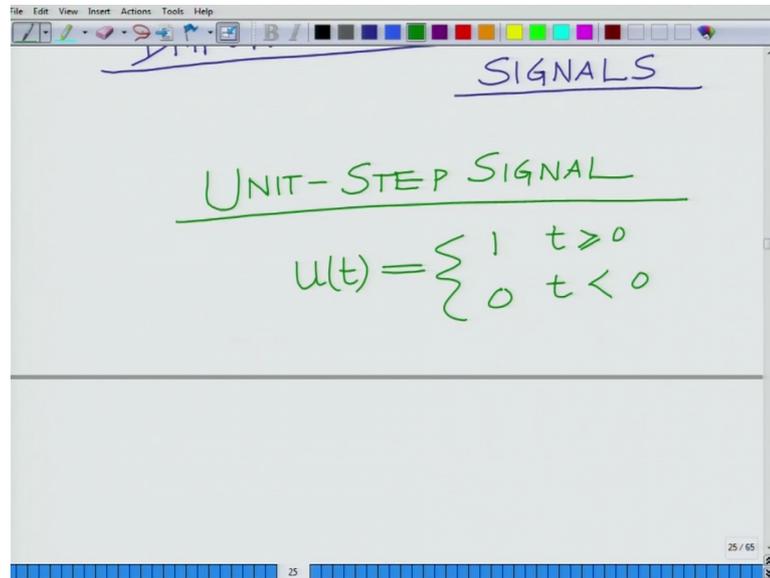

(Refer Slide Time: 05:03)

Again is example of power signal is again $\sin 2\pi ft$ the sinusoid is a classic example of a power signal now with that we come to the end of the classification of signals. So, we have covered most of the major classes of signals now let us look at some important continuous and discrete time signals which occur very frequently alright its essential to understand some of these signals because these occur very frequently in applications and in the analysis of signals and systems.

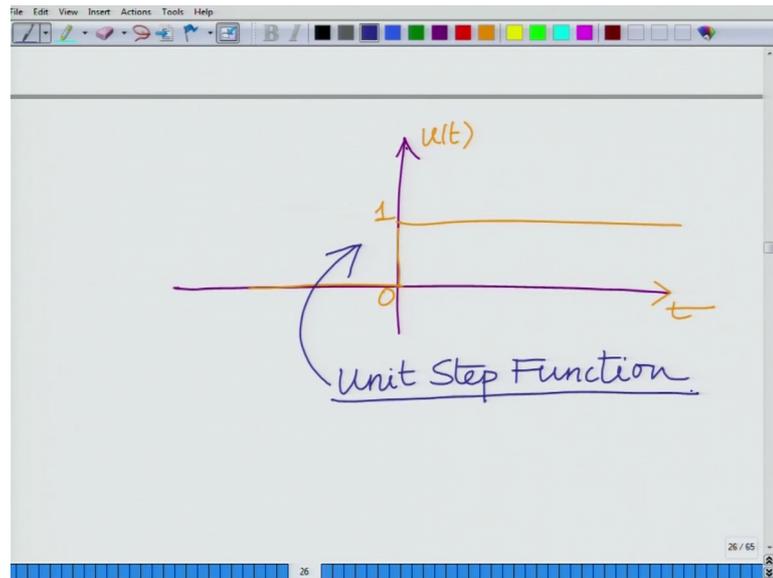

So, what we are going to look at next is basically some important continuous important continuous time signals for instance the first important signal is what you must be very familiar with which is the unit step signal which you also been using several points.

(Refer Slide Time: 06:33)

$$u(t) = \begin{cases} 1 & t \geq 0 \\ 0 & t < 0 \end{cases}$$

Before the unit step signal is defined as its represented as $u(t)$ and its defined as one for t greater than equal to 0 0 for t equal to 0 and also for t equal to 0 you can sometimes define it as one half alright. So, it is defined as 1 for t greater than equal to 0; 0 for t less than 0 and; obviously, you can see at t equal to 0. There is a discontinuity there is a jump discontinuity ok.

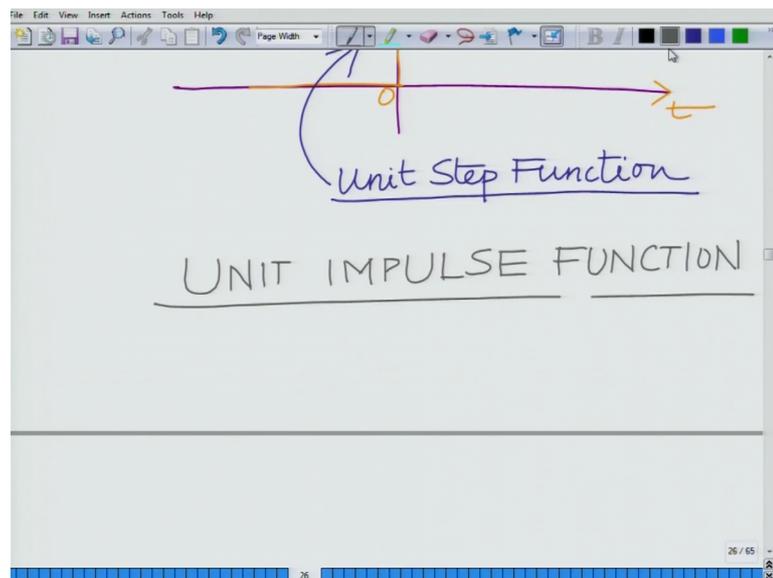

(Refer Slide Time: 07:04)

So, this is basically your unit this is basically your unit step signal which looks something like this. So, this is time equal to 0, it jumps from 0 to 1. So, this is your unit step function this is also known as this is the unit step signal or unit step function also known as the unit step also known as the unit step function ok.

And another such signal important signal is the unit impulse function this is the unit.

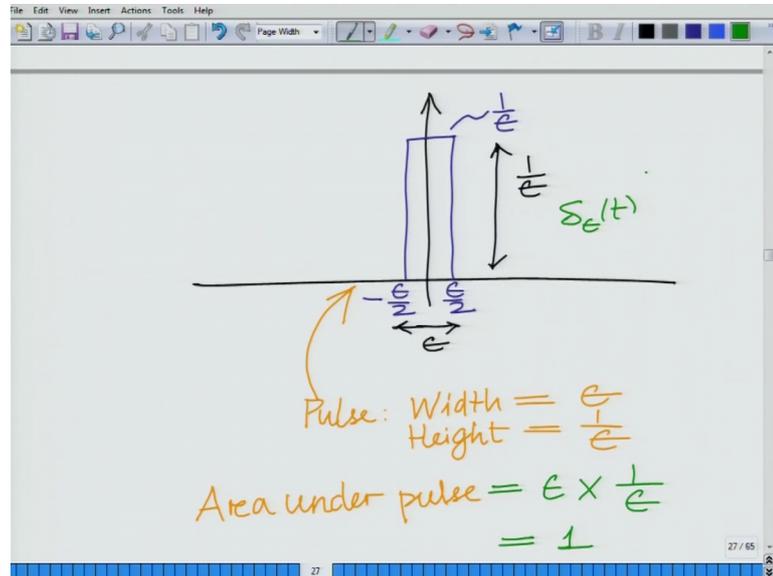

(Refer Slide Time: 08:04)

And this is one of the most fundamental one of the most interesting and one of the most; I would say, key signals to understand the various properties or the behavior or

understand the properties and model the behavior of system and its definition as is as follows.

(Refer Slide Time: 08:37)

Consider the following signal which is a pulse which is a pulse well which is basically it is a pulse, it looks as follows the pulse from minus ϵ by ϵ by 2 to ϵ by 2 and is of height one over ϵ . So, the pulse has. So, the width equals ϵ and a height equals one over ϵ . So, consider this pulse. So, this is a pulse of width equals ϵ height equals one over ϵ . So, that the area under the pulse.

Equals will the area under the pulse equals ϵ into $\frac{1}{\epsilon}$ equals 1. So, this is the area under pulse now consider. So, basically we denote this pulse by $\delta_\epsilon(t)$. So, this is a sequence of pulses 1 pulse for each value of ϵ . So, we are considering a narrow pulse with width ϵ from minus ϵ by 2 to ϵ by 2 and of height $\frac{1}{\epsilon}$.

(Refer Slide Time: 10:48)

The image shows a whiteboard with handwritten mathematical expressions. At the top, there is a green equation: $\int_{-\infty}^{\infty} \delta_{\epsilon}(t) dt = 1$. Below this, another green equation defines the impulse function: $S(t) = \lim_{\epsilon \rightarrow 0} \delta_{\epsilon}(t)$. An arrow points from the text "impulse Function" to the $S(t)$ term. The whiteboard interface includes a menu bar (File, Edit, View, Insert, Actions, Tools, Help) and a toolbar with various drawing tools. The page number "28 / 65" is visible in the bottom right corner.

So, the area under the pulse is unity. So, basically what we have is for each pulse delta epsilon t for every epsilon we have the area under pulse equal to 1.

Now, we define the pulse delta t as basically limit of epsilon tends to 0 of delta epsilon t and this is your impulse; impulse function or simply known as the impulse that is as epsilon tends to infinity the width epsilon goes to 0 epsilon tends to 0 width.

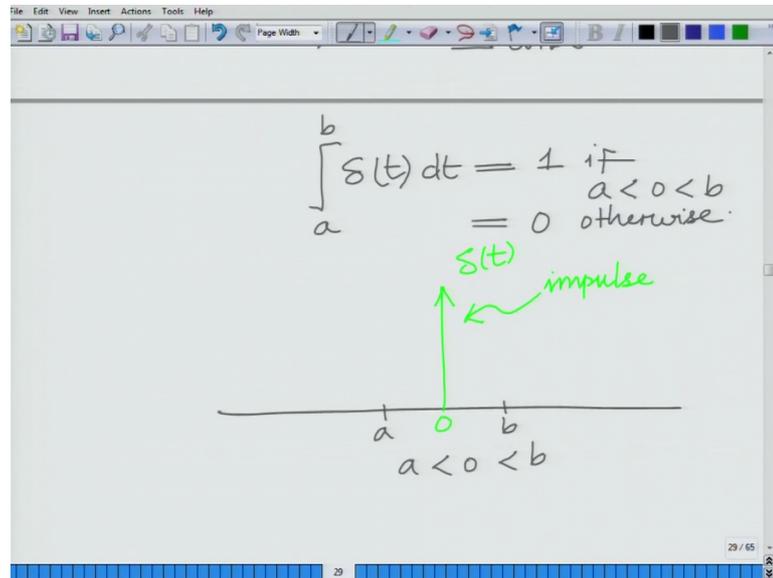

(Refer Slide Time: 11:48)

The image shows a whiteboard with handwritten mathematical expressions. At the top, there is a green equation: $S(t) = \lim_{\epsilon \rightarrow 0} \delta_{\epsilon}(t)$. An arrow points from the text "impulse Function" to the $S(t)$ term. Below this, there are blue notes: "As $\epsilon \rightarrow 0$ ", "Width $\epsilon \rightarrow 0$ ", "Height $\frac{1}{\epsilon} \rightarrow \infty$ ", and "But, Area = 1 = constant". The whiteboard interface includes a menu bar (File, Edit, View, Insert, Actions, Tools, Help) and a toolbar with various drawing tools. The page number "28 / 65" is visible in the bottom right corner.

Epsilon goes to 0 height 1 over epsilon tends to infinity, but the area under it still remains constant that is unity. So, as epsilon tends to infinity as epsilon tends to 0 the width of the

pulse epsilon tends to 0 the height one over epsilon tends to infinity, but the area is equal to 1 which is a the area is always equal to 1 which is a which is a constant. So, basically what you can see is that the area under this in fact.

(Refer Slide Time: 12:35)

If you look at any integral a to b delta t dt equal to one if 0 if a is less than 0 less than b.

That is you have your impulse which is denoted by let us just draw the impulse at 0. So, this is your impulse this is your impulse that is delta t and if you integrate it over any interval a comma b such that a less than 0 and b is strictly greater than 0 that is if you consider its integral over any interval a to b such that a lies to the left of 0 and b lies to the right of 0 the integral from a to b of the impulse is always the unity; obviously, if either both a and b lie to the left of 0 or both a and b right at the right of 0 that is any interval which does not include the support of the impulse then the integral is 0.

so we have this is this integral is equal to 0 otherwise and if either a or b is equal to 0 then the integral is not defined it is not proper. It is not defined its undefined that is something that is to keep in mind and this has a very interesting as I have already told you it is a very interesting signal and it has several interesting properties for instance one thing that you can show here is that.

(Refer Slide Time: 14:39)

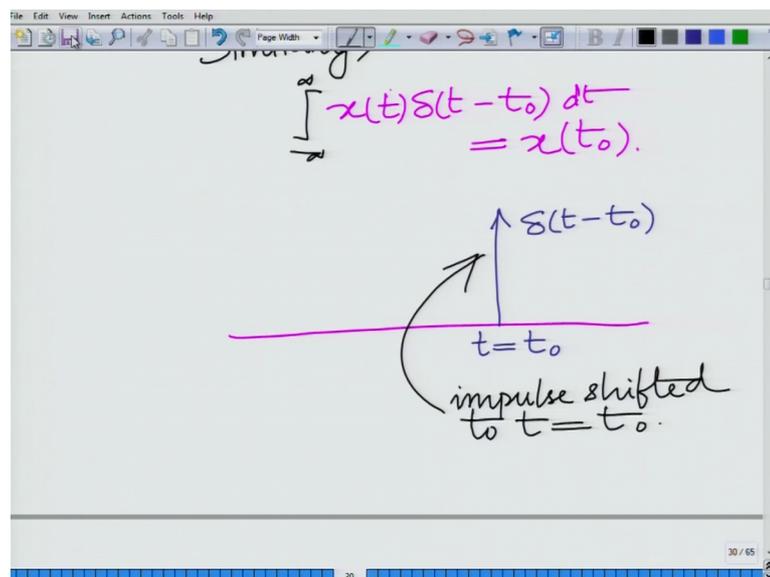

Properties: $\int_{-\infty}^{\infty} x(t)\delta(t) dt = x(0)$

Similarly,

$$\int_{-\infty}^{\infty} x(t)\delta(t-t_0) dt = x(t_0)$$

Integral; its properties are as follows integral minus infinity to infinity $x(t)\delta(t) dt$. This is equal to $x(0)$ that is if you multiply $\delta(t)$ impulse function by any signal $x(t)$ and integrate it from minus infinity to infinity it picks the value of the function $x(t)$ at $t=0$ that is value of the function $x(t)$ at $t=0$ now similarly integral minus infinity to infinity $x(t)\delta(t-t_0) dt = x(t_0)$.

(Refer Slide Time: 16:00)

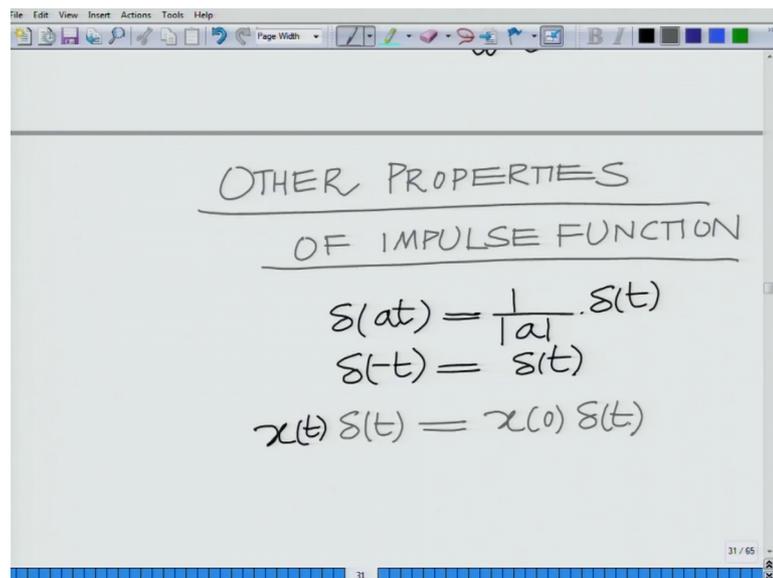

Now, remember $\delta(t-t_0)$ is nothing, but basically your impulse shifted that is $\delta(t-t_0)$ denotes your impulse that is shifted to $t=t_0$.

impulse shifted to t equal to t naught. So, if you multiply this by x of t delta x of t into δt minus t naught and integrate it from minus t infinity to infinity what we have is the signal x at t naught that is x of t naught ok.

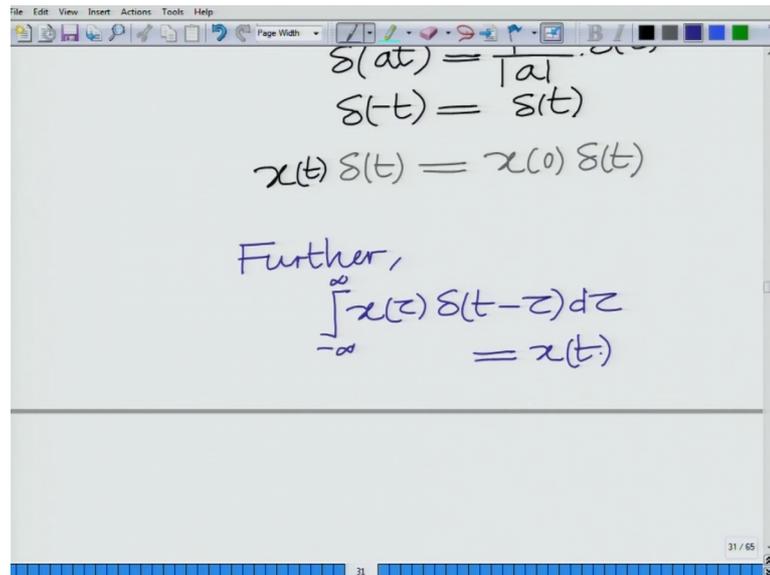

Now, there are several other interesting properties of impulse function for instance the other some of the other properties which you can also show for the impulse function.

(Refer Slide Time: 16:57)

That is other properties of and these are very important properties because the impulse function some of the other properties of the impulse function are δat equals one over magnitude a of δt δ minus t equals δt and for any signal x x t times δt equals x of 0 times δt . So, these are some of the other properties further.

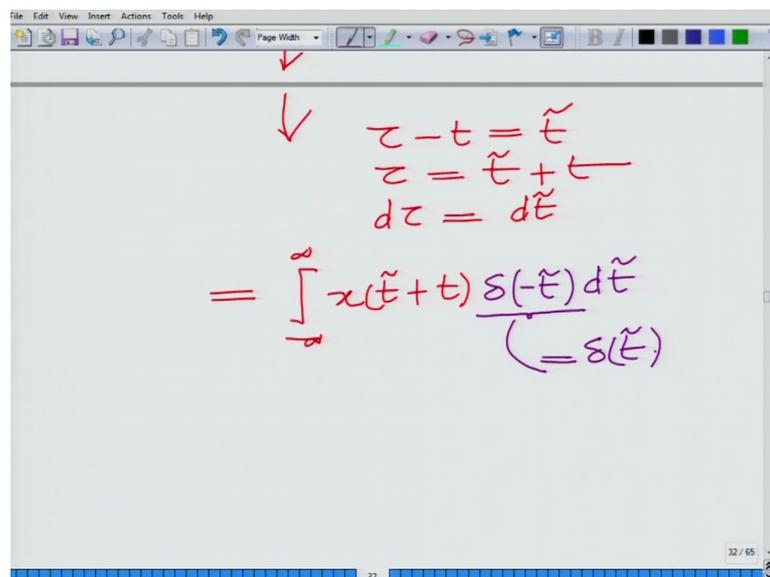

(Refer Slide Time: 18:13)

The image shows a whiteboard with handwritten mathematical equations. At the top, it states $\delta(at) = \frac{1}{|a|} \delta(t)$. Below that, it shows $\delta(-t) = \delta(t)$. The next line is $x(t) \delta(t) = x(0) \delta(t)$. Further down, it says "Further," followed by the integral equation $\int_{-\infty}^{\infty} x(\tau) \delta(t-\tau) d\tau = x(t)$. The whiteboard interface includes a menu bar at the top with "File", "Edit", "View", "Insert", "Actions", "Tools", and "Help". A status bar at the bottom indicates "31 / 65".

What we also have is another very interesting property if you consider integral minus infinity to infinity x of τ delta t minus τ $d\tau$ this can be shown to be equal to x of t this is a very important property what you can show is x of x of τ integral minus infinity to infinity x of τ delta t minus τ $d\tau$ is x of t ; let us try to see; how we can demonstrate this or prove this property.

(Refer Slide Time: 18:58)

The image shows a whiteboard with handwritten mathematical equations. It starts with a red arrow pointing down to the equation $\tau - t = \tilde{\tau}$. Below that, it shows $\tau = \tilde{\tau} + t$ and $d\tau = d\tilde{\tau}$. The final equation is $= \int_{-\infty}^{\infty} x(\tilde{\tau} + t) \delta(-\tilde{\tau}) d\tilde{\tau}$, with a note in purple that $(= \delta(\tilde{\tau}))$. The whiteboard interface includes a menu bar at the top with "File", "Edit", "View", "Insert", "Actions", "Tools", and "Help". A status bar at the bottom indicates "32 / 65".

So, here what we are going to do is we are going to set τ minus t equals $\tilde{\tau}$ which means τ becomes equal to $\tilde{\tau}$ plus t and $d\tau$ will be equal to $d\tilde{\tau}$

tilde. So, the integral simplifies as integral minus infinity to infinity $x(t)$ plus t times $\delta(t)$ minus $\delta(t)$ minus t , but t minus t is minus t $d t$ equals $d t$ equals $d t$ tilde.

Now, here we use the property that $\delta(t)$ minus t tilde equals $\delta(t)$ tilde.

(Refer Slide Time: 20:06)

The whiteboard shows the following steps:

$$d\tau = dt$$

$$= \int_{-\infty}^{\infty} x(\tilde{t} + t) \delta(-\tilde{t}) d\tilde{t}$$

(= $\delta(\tilde{t})$)

$$= \int_{-\infty}^{\infty} x(\tilde{t} + t) \delta(\tilde{t}) d\tilde{t}$$

$$= x(\tilde{t} + t) \Big|_{\tilde{t} = 0}$$

$$= x(t)$$

Which implies this becomes minus infinity to infinity $x(t)$ plus t into $\delta(t)$ times $d t$, but $x(t)$ plus t $\delta(t)$ is nothing, but $x(t)$ plus t evaluated at t equals evaluated at t equals 0. So, this is equal to simply $x(t)$.

(Refer Slide Time: 20:54)

The whiteboard shows the following steps:

$$= x(t)$$

$$\int_{-\infty}^{\infty} x(\tau) \delta(t - \tau) d\tau = x(t)$$

"Sifting" property of impulse function.

So, what we have as a result is that integral minus infinity to infinity x of tau delta x of tau delta; delta t minus tau d tau equals x or. So, what we have is let me just write it integral minus infinity to infinity x of tau delta t minus tau d tau equals x of t and this property is known as the; this property is known as the this is known as the sifting property of the impulse function this is the sifting property. So, this property is known as the; this property is known as the sifting property of the impulse function or the sifting property of the delta function.

So, this is; so, the delta function we have looked at the delta function it has it has a very interesting at a complicated definition; it is not easy to understand. So, I urge you to take a look at this again and it has a lot of interesting properties. So, it would be good to examine and understand the properties of the impulse functions because this arises very frequently in the analysis of signals and systems and its very important to both understand the behavior and also model and understand the behavior of systems and we will see several applications of this impulse function as we go through the rest of this course ok.

Let us come to another interesting function that occurs frequently which is the complex exponential.

(Refer Slide Time: 23:01)

COMPLEX EXPONENTIAL

$$x(t) = e^{j\omega t} = \cos(\omega t) + j\sin(\omega t)$$

$j = \sqrt{-1}$

$$|x(t)| = \sqrt{\cos^2(\omega t) + \sin^2(\omega t)}$$

$$= 1$$

The complex exponential function is defined as e to the power of j omega naught t or e to the power of j 2 pi f t which is basically cosine omega naught t plus j sin omega naught t

where j equals square root of minus one is the imaginary number square root of minus one and if you can look if you look at if you $x(t)$ equals e to the power of j omega naught t you have magnitude of $x(t)$ which is equal to square root of cosine square omega naught t plus sin square omega naught t equals one. So, magnitude of $x(t)$ is always one that is a complex exponential always has unit magnitude e to the power of j omega naught t its magnitude is 1 and further it is a periodic signal.

(Refer Slide Time: 24:27)

The image shows a whiteboard with the following handwritten content:

$$|x(t)| = \sqrt{\cos^2(\omega_0 t) + \sin^2(\omega_0 t)}$$

$$= 1$$

$$e^{j2\pi f_0 t} = e^{j\omega_0 t}$$

$f_0 = \frac{\omega_0}{2\pi}$

$\underbrace{\hspace{1.5cm}}_{\text{Hz}} \quad \underbrace{\hspace{1.5cm}}_{\substack{\text{Angular Frequency} \\ \text{Radian/sec.}}}$

34 / 65

It can also be represented as e to the power of $j 2 \pi f$ naught t equals e to the power of j omega naught t where f naught equals omega naught divided by 2π this is an important relation omega naught is the circular frequency this is also known as the angular frequency this is in radians per second the unit of this and the unit of f naught frequency is hertz and this is your circular cover angular frequency.

(Refer Slide Time: 25:22)

Handwritten notes on a whiteboard:

$$f_0 = \frac{\omega_0}{2\pi}$$

Hz Angular Frequency
Radian/sec.

$$\text{Period } T = \frac{1}{f_0} = \frac{2\pi}{\omega_0}$$
$$f_0 = 5 \text{ Hz}$$
$$\Rightarrow T = \frac{1}{5} = 0.2 \text{ s.}$$

And period this is a periodic signal its period T equals one over f_0 equals 2π over ω_0 . So, the period for instance if f_0 equals five hertz implies T equals one over five seconds which is equal to point two seconds that is the meaning. So, the period is basically the reciprocal of the frequency ok.

(Refer Slide Time: 26:11)

Handwritten notes on a whiteboard:

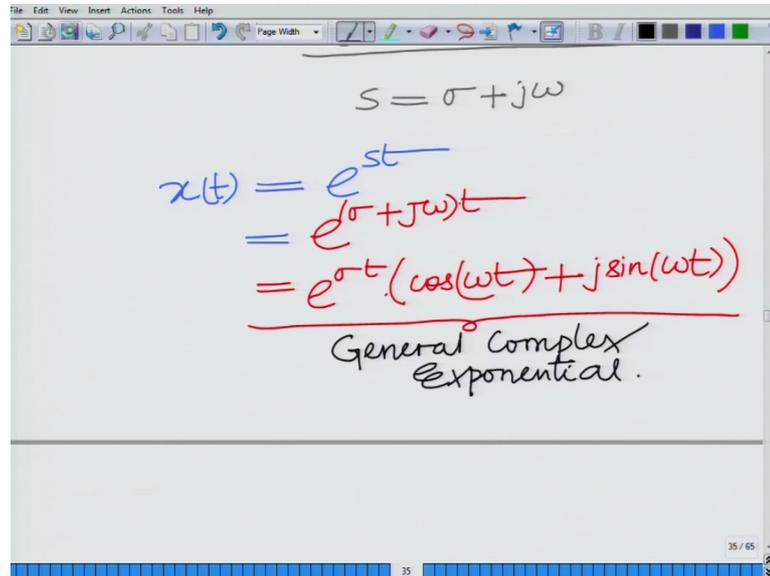

GENERAL COMPLEX
EXPONENTIAL :

$$s = \sigma + j\omega$$
$$x(t) = e^{st}$$

And a general complex exponential is now defined as something a general complex exponential a general complex exponential is defined as follows s equal to σ plus j

omega and xt equals e to the power of s t which is basically equal to this as a general complex exponential.

(Refer Slide Time: 26:54)

The image shows a handwritten derivation on a whiteboard. At the top, the complex frequency variable is defined as $s = \sigma + j\omega$. Below this, the signal $x(t)$ is expressed as e^{st} . This is then expanded to $e^{(\sigma + j\omega)t}$. Finally, it is written as $e^{\sigma t} (\cos(\omega t) + j \sin(\omega t))$. A red horizontal line is drawn under the final expression, and the text "General Complex Exponential." is written below it.

$$s = \sigma + j\omega$$
$$x(t) = e^{st}$$
$$= e^{(\sigma + j\omega)t}$$
$$= e^{\sigma t} (\cos(\omega t) + j \sin(\omega t))$$

General Complex Exponential.

Which is e to the power of x t equals e to the power of s t which is equal to well e to the power of sigma plus j omega t which is e to the power of sigma t into cosine omega t plus j sin of omega t. So, this is your general complex alright. So, what we have seen in this module is we have seen yet a different other different classes of signals such as energy and power signals etcetera we have also seen some very commonly arising and important continuous time signals such as the unit impulse or such as the unit step signal or the unit step function the unit impulse function and we have also seen the complex exponential and the general complex exponential signals. So, we will stop here and continue with other aspects in the subsequent modules.

Thank you very much.
