

Course name: EMI /EMC and Signal Integrity: Principles, Techniques and Applications.

Professor name: Prof. Amitabha Bhattacharya

Department name: Electronics and Electrical Communication Engineering

Institute name: IIT Kharagpur

Week :06

Lecture 27: Determination of Per Unit Length Inductance (Continued)

Welcome to the 27th lecture of the course on EMIMC and Signal Integrity Principles, Techniques and Applications. We were discussing determination of per unit length inductance in our previous lecture that we are continuing. We have seen that the total flux linked by the single current, single isolated current that it contributed only by the circumference the surface that is cylindrical surface of the open transverse surface. So that we will now evaluate by integration because the field is varying with r , so we will have to be careful there, so that will be simply the for an unit length per unit length means the surface now the this surface I can say that this whatever surface I am seeing that is of length is 1, so only the radius matters, so that means I can write $B \cdot t$ instead of ds we have already seen that it has become instead of a vector product it is a just simple multiplication. So $B \cdot t \cdot ds$ will become $B \cdot t \cdot dr$ and this will be from r_1 the nearer part to the further part, so r_1 to r_2 and let us put the value of $B \cdot t \cdot r_1 \cdot r_2 \cdot \mu \cdot i \cdot i$ is i enclosed by $2 \pi \cdot dr$, so that will give us $\mu \cdot i$ by $2 \pi \cdot \ln r_2$ by r_1 where for reminder we are saying that r_2 is greater than r_1 and the unit will be Weber because it is flux. So now instead of isolated where we consider a two-wire system carrying equal currents i in opposite direction, so our picture is somewhere two wires are there and let us say that they are carrying opposite directed current, so in one where if I assume this the other one I will be using this and this one let us say its radius is r_{w1} where that is why this one let us say that its radius is r_{w2} and the separation between their two centers that is s and let us join a hypothetical line here, so this current is flowing inside, so I will apply right hand rule to find the flux, so the flux will be in this direction I will say it is $\pi \cdot m_1$ now for this it is coming out, so this is also in the same direction that means the total flux will be added, so total flux of these two conductor system will be $\pi \cdot m_1$ plus $\pi \cdot m_2$ now already we have got expression. Now here I forgot to tell you that what whenever we are using two conductor system definitely there will be proximity effect the magnetic field will get distorted etcetera but so that means whatever we have derived for an isolated wire will not hold good here but we are neglecting the proximity effect we are considering in our model as if the two wires are isolated which is not the case but that is the flow of our model or assumption of our model if you want more realistic picture you will have to take it for a better model you will have to develop. So now we can put the values that this is $\mu \cdot y \cdot i$ is same in both $\mu \cdot y$ by $2 \pi \cdot \ln r_2$ what is r_2 you see in this case r_2 means

up to this one so what is r_2 here can I say that s minus r_2 is r_2 so my expression will be s minus r_2 by what is r_1 , r_1 is r_1 means here so that I can write as r_1 this is for ψ_{m1} and for ψ_{m2} I will write μy by $2\pi \ln$ for it by similar way I can say that r_2 in this case will be s minus r_1 by it will be r_2 . Here we are assuming that the two wires are of different radius this is a general expression.

A hand-drawn diagram on a whiteboard shows a cylindrical shell with inner radius r_1 and outer radius r_2 . The shell is labeled with 'top' and 'bottom' ends. A magnetic field vector \vec{B}_T is shown pointing radially inward. A green oval encloses the shell. To the right, the magnetic flux Ψ_m is calculated as the surface integral of $\vec{B}_T \cdot d\vec{s}$ over the shell's surface. The calculation is split into three parts: a cylindrical surface integral, a top surface integral, and a bottom surface integral. The top and bottom integrals are marked with red '0' and '0' respectively, indicating they are zero.

$$\Psi_m = \iint_S \vec{B}_T \cdot d\vec{s}$$

$$= \iint_{\text{cylindrical}} \vec{B}_T \cdot d\vec{s} + \iint_{\text{top}} \vec{B}_T \cdot d\vec{s} + \iint_{\text{bottom}} \vec{B}_T \cdot d\vec{s}$$

LECTURE 27: DETERMINATION OF PER UNIT LENGTH INDUCTANCE (CONTD.)

A hand-drawn diagram on a whiteboard shows two parallel wires with radii r_{w1} and r_{w2} separated by a distance s . The left wire has current I into the page (\otimes) and the right wire has current I out of the page (\odot). Magnetic flux lines ψ_{m1} and ψ_{m2} are shown between the wires. To the right, the magnetic flux Ψ_m is calculated as the integral of B_T over the distance s between the wires. The result is $\frac{\mu I}{2\pi} \ln\left(\frac{R_2}{R_1}\right)$ Wb, where $R_2 > R_1$. Below this, the total flux Ψ_m is expressed as the sum of fluxes from each wire, leading to the final expression: $\frac{\mu I}{2\pi} \ln\left(\frac{s-r_{w2}}{r_{w1}}\right) + \frac{\mu I}{2\pi} \ln\left(\frac{s-r_{w1}}{r_{w2}}\right)$.

$$\Psi_m = \int_{R_1}^{R_2} B_T dn = \int_{R_1}^{R_2} \frac{\mu I}{2\pi n} dn = \frac{\mu I}{2\pi} \ln\left(\frac{R_2}{R_1}\right) \text{ Wb}$$

$$R_2 > R_1$$

$$\Psi_m = \Psi_{m1} + \Psi_{m2}$$

$$= \frac{\mu I}{2\pi} \ln\left(\frac{s-r_{w2}}{r_{w1}}\right) + \frac{\mu I}{2\pi} \ln\left(\frac{s-r_{w1}}{r_{w2}}\right)$$

so ψ_m is μy by 2π the total flux of the system $\ln s$ minus r_{w1} into r_s minus r_{w2} by r_{w1} into r_{w2} . Now here we can further simplify we can make some assumption that s is the separation of the two wires separation between their centers that in general is much larger than radius of either of the wire so our assumption is s is much larger than r_{w1} s is also much larger than r_{w2} so that means in the numerator we can write $2\pi \ln s$ square by r_{w1}, r_{w2} . So if actually this assumption this is if s by r_{w1} is greater than 5 or s by r_{w2} is greater than 5 this assumption is justified or the result that will come up from this assumption that will be accurate up to 3 percent within 3 percent the error will be. If you want more realistic more accurate result you should not do this, this equation you can put the values but we are proceeding with this assumption knowing that 3 percent accurate result will get. So now we have related flux with current so we can easily find what is l or l external to be specific but let us say that we will call this l so because internal inductance is not more that is simply flux of the system by current that is μ by $\pi \ln s$ by r_{w1}, r_{w2} and inductance is henry per meter per unit length inductance. Now if both wires are same then we put r_{w1} is equal to r_{w2} and that time l becomes μ here μ by π this will be s square μ by i now s square by r_w square so that can come out and I can write μ by $\pi \ln s$ is equal to let us say r_w is s by henry per meter.

$$\psi_m = \frac{\mu I}{2\pi} \ln \left[\frac{(s - r_{w1})(s + r_{w2})}{r_{w1} r_{w2}} \right]$$

$$\left. \begin{array}{l} s \gg r_{w1} \\ s \gg r_{w2} \end{array} \right\} \begin{array}{l} \frac{s}{r_{w1}} > 5 \\ \frac{s}{r_{w2}} > 5 \end{array} \quad 3\% \text{ accuracy}$$

$$= \frac{\mu I}{2\pi} \ln \left(\frac{s^2}{r_{w1} r_{w2}} \right)$$

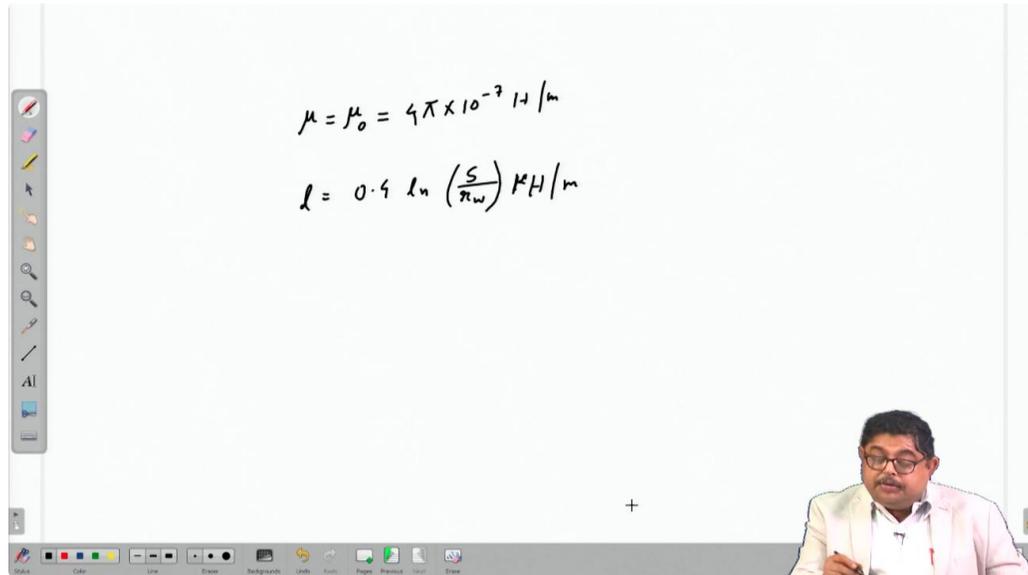

$$l = l_{ext} = \frac{\psi_m}{I} = \frac{\mu}{\pi} \ln \left(\frac{s^2}{r_{w1} r_{w2}} \right) \text{ H/m}$$

$$r_{w1} = r_{w2} = r_w$$

$$l = \frac{\mu}{\pi} \ln \left(\frac{s^2}{r_w^2} \right) \text{ H/m}$$

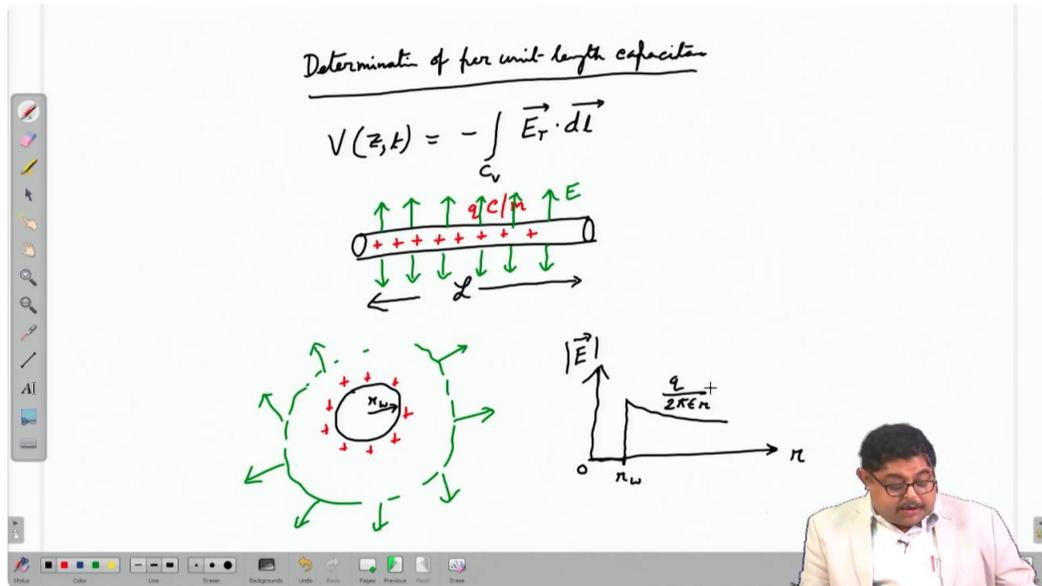

Now if we put the value of μ if μ is equal to μ_0 that means it is in free space or the medium between the two transmission two lines are free space then it is μ_0 and you know the value of μ_0 $4\pi \times 10^{-7}$ henry per meter. So you get l is equal to if you do the calculation $0.54 \ln s$ by r_w henry micro henry per meter I have absorbed that 10^{-6} there in micro henry per meter. Now

so this is about determination of an inductance that means from the geometry and the medium you saw that if we know the separation distance if we know the wire radius and if we know the intervening medium then you can derive the per unit length capacitance per unit length inductance.

Now let us go to determination of per unit length capacitance. So, here again we have seen the transmission line can be analyzed in a static way. So we can write $V = \int_{-\infty}^{\infty} \mathbf{E} \cdot d\mathbf{l}$ is equal to minus contour across any path $\oint \mathbf{E} \cdot d\mathbf{l} = -\frac{Q}{C}$. So again consider a an isolated conducting wire carrying a per unit length charge distribution Q coulomb per meter. So let us say that there are charge in the line it is like static case so this distribution is Q coulomb per meter and this length first let us call l actually determination time will put l is equal to 1 and we know that if we have this type of charge what will happen to the electric field electric field will be like this again we are not considering the end points because at the end there will be some fringing etcetera all those we are neglecting. So there will be this is the green colored ones are the electric field that will come out from here \mathbf{E} fields. So now we know that because of symmetry the that means basically if I now see the cross section of the wire so it is R_w here and the charge is on the outside surface because in the conductor there cannot be any charge so this charge distribution is like this and let us consider a Gaussian surface and from that we know that this electric field will be like this symmetrical because the charge distribution is symmetrical and you know all of you will be able to plot the what is the \mathbf{E}

versus R distribution so this is your E magnitude that you know that up to R w there is not anything unlike the magnetic case where inside also there are magnetic fields but here this will be 0 sorry 0 this is R w and then we will get suddenly a jump in the electric field and then we have seen that it falls down with a 2 pi by epsilon simply by doing Gauss's law applying Gauss's law you can find this out that this will be the electric field distribution.

Now to determine this transverse electric field we consider a cylindrical Gaussian surface of radius R so let me take a cylinder and its radius is R w and let me take a Gaussian surface around it and now let me take that this cylinder is length is 1 meter and we know since the from our previous structure that the fluxes are all going away that means they are all like this so this top does not contribute any flux because the top in top there is the ds vector that is on top but E t is going away so now we can write the equation which governs this that is epsilon E t dot ds is equal to q enclosed so no flux from the top no flux from the bottom so only the cylindrical curved surface contributes to flux so and that flux you can easily calculate by your knowledge of Gauss's law that it will be q into 1 by epsilon 2 pi R into 1 is equal to q by 2 pi epsilon R volts per meter. Now again the same question that if we have this surface we will have to find the flux electric flux now inside there is no flux so in this cylindrical portion what is the flux so if I call this as R1 from the center and this distance is R2 from the center so in this cylindrical surface that means in the transverse plane what is the flux that is got.

$$\oint_S \vec{E}_r \cdot d\vec{s} = Q_{\text{enclosed}}$$

$$E_r = \frac{q \times l}{\epsilon \{ (2\pi r) \times l \}} = \frac{q}{2\pi \epsilon r} \text{ V/m}$$

So, before that let us find the question that suppose pose the question like this suppose I have a charge here let the charge is like this plus q charge and what is the voltage that is there between two points suppose arbitrarily I am taking one point B that is at distance R_1 from the charge this is a point charge I have shown it in bigger way but this is a point charge and another point let us say at B deliberately I have taken A further away from B and let its distance is called R_2 so R_2 is greater than R_1 and what is the voltage between the point A and B where I am starting the integral from A I am going to be $E \cdot dl$ I am finding so basically I am finding what is V_{BA} so I can go line integral so I can go on any path like this to reach this let us call this path as C. So, since I am going from A to B so let me call that this is at A is at a lower potential and B is at a higher potential. So, instead of these an equivalent problem is I can write like this that same charge q and I am first going to A from here that is I am going to A and then from there I am taking a semicircular path or let me put it in dash this is my path of integration A and then from there this is my point B this is R_1 so I am coming back in this path this will also do so let me call that this is my C_2 this is my C_1 so I am reaching here so that means first I am starting from here I am going by C_2 this is a part of a circle with radius R_2 I am reaching at this point and then coming back these are same because for line integral it is immaterial what path I take and I know that all the ETs are like this from the charge distribution you see ET will be like this. So, let us take the integral V_{BA} that is our objective that is minus $\int_C E \cdot dl$ I can break these originally it was path C I can breaking it into C_1 $E \cdot dl$ minus C_2 first I am going by C_2 so let me write the C_2 then C_1 $E \cdot dl$. So along C_2 you see ET and dl vectors what will be dl vectors these are my dl vectors at various points so dl and C_2 ET they are orthogonal so that means

this part will go out this will give rise to 0 only along this point the ET and dl they are in the same direction so I can write now VBA is equal to minus C1 ET dot dl is equal to minus C1 means I am starting from R2 because these distance is R2 and these distance is R1 ET dot dl I know the value of ET what is ET Q by 2 pi epsilon R and dl I am writing as dr because in this path they are same .

The whiteboard contains the following content:

- Diagram 1:** Two concentric cylinders with radii R_1 and R_2 . The inner cylinder is at potential b^+ and the outer is at a^- . A path C is shown between them. The condition $R_2 > R_1$ is noted.
- Equation 1:**
$$V_{ba} = - \int_{C_1} \vec{E}_r \cdot d\vec{l}$$
- Equation 2:**
$$= - \int_{C_2} \vec{E}_r \cdot d\vec{l}$$
- Equation 3:**
$$= - \int_{R_2}^{R_1} \frac{q}{2\pi\epsilon n} dn$$
- Diagram 2:** Similar to Diagram 1, but with a dashed path C_1 and C_2 and a differential element dl shown. Electric field vectors E_r are also indicated.

so I can see that VBA will become Q by 2 pi epsilon ln R2 by R1 volts where R2 is greater than R1. Just similarly you can do yourself a problem that if you have a negative charge distribution for that you will see that VBA you will have to redo just do not put Q is equal to minus because many things are different there but this will give rise to the result I am doing anyone can easily do it but you will have to do it ln R1 by R2 with this

The whiteboard contains the following content:

- Equation 1:**
$$V_{ba} = \frac{q}{2\pi\epsilon} \ln\left(\frac{R_2}{R_1}\right) \quad R_2 > R_1$$
- Diagram:** A small circle with a red '+' sign and the letter 'q' inside, representing a charge distribution.
- Equation 2:**
$$V_{ba} = \frac{q}{2\pi\epsilon} \ln\left(\frac{R_1}{R_2}\right)$$

now we are in a position to see what happens if we have two conductors one is positively charged another is negatively charged again we have brought we are not considering any proximity etc. so this is r_{w1} this is r_{w2} and this distribution is plus Q coulomb per meter this distribution is minus Q coulomb per meter so what is our V ? V will be for this one this isolated one Q by $2\pi\epsilon_0 \ln S$ minus r_{w2} again you see that what is the maximum oh I have not put the S part so S is the distance between the two centers so R_2 is in this case S minus r_{w2} by r_{w1} plus Q by $2\pi\epsilon_0 \ln r_{w2}$ by S minus r_{w1} . Q charge this Q I assume actually this Q if positive and negative both are together this Q will become a minus Q this portion is so this will be again Q by $2\pi\epsilon_0 \ln S$ minus r_{w1} into S minus r_{w2} by $r_{w1} r_{w2}$.

$$V = \frac{q}{2\pi\epsilon} \ln\left(\frac{S - r_{w2}}{r_{w1}}\right) + \frac{(-q)}{2\pi\epsilon} \ln\left(\frac{r_{w2}}{S - r_{w1}}\right)$$

$$= \frac{q}{2\pi\epsilon} \ln\left[\frac{(S - r_{w1})(S - r_{w2})}{r_{w1} r_{w2}}\right]$$

Then assuming S is much larger than $r_{w1} r_{w2}$ we get V is equal to Q by $2\pi\epsilon_0 \ln S$ square by $r_{w1} r_{w2}$ then taking r_{w1} is equal to r_{w2} is equal to r_w we get V is equal to Q by $\pi\epsilon_0 \ln S$ by r_w and then per unit length capacitance C is equal to Q by V is equal to $\pi\epsilon_0$ by $\ln S$ by r_w . So, if ϵ_0 is equal to ϵ_0 naught C becomes you can put the value ϵ_0 naught means 1 by 36π into 10 to the power 36π into 10 to the power minus 9 farad per meter if you put this value it will be 27.78 by $\ln S$ by r_w pico farad per meter. So, you can cross check we have got L we have got C what is the $L C$ this is you can put the value it will come as 1.11 into 10 to the power minus 17 and you can see that this is $L C$ will be equal to μ_0 into ϵ_0 naught. So, you can μ_0 naught into ϵ_0 naught you can put that value. So, as I said that 1 by this will be 1 by root over $L C$ should be coming to 2.999 into 10 to the power 8 meter per second which is the velocity of light in free space. So, we have determined both inductance and

capacitance from first principles. Now, we will see some practical problems in the next class. Thank you.

The whiteboard contains the following handwritten text and equations:

$$S \gg r_{w1}, r_{w2}$$
$$V = \frac{q}{2\pi\epsilon} \ln\left(\frac{S^2}{r_{w1}r_{w2}}\right)$$
$$r_{w1} = r_{w2} = r_w$$
$$V = \frac{q}{\pi\epsilon} \ln\left(\frac{S}{\pi r_w}\right)$$
$$C = \frac{q}{V} = \frac{\pi\epsilon}{\ln\left(\frac{S}{\pi r_w}\right)}$$
$$\epsilon = \epsilon_0 = \frac{1}{36\pi} \times 10^{-9} \text{ F/m}$$
$$C = \frac{27.78}{\ln\left(\frac{S}{\pi r_w}\right)} \text{ pF/m}$$

Additional calculations on the right side of the board:

$$LC = 1.11 \times 10^{-17}$$
$$\frac{1}{\sqrt{LC}} = 2.999 \times 10^8 \text{ m/s}$$

A small video inset in the bottom right corner shows a man with glasses and a light-colored shirt, likely the instructor.
