**Lecture – 11**  
**Optimal of Functional with Conditions**

Welcome friends, today's class is on the optimum of functional with condition. So, we will find out the optimum value of a given functional which is subjected to the condition, we can formulate the problem in the following manner.

(Refer Slide Time: 00:51)

**Optimum of Functional with Conditions**

Consider the extremization of the functional

$$J(x_1(t), x_2(t), t) = J = \int_{t_0}^{t_f} V(x_1(t), x_2(t), \dot{x}_1(t), \dot{x}_2(t), t) dt$$

subject to the condition  $g(x_1(t), x_2(t), \dot{x}_1(t), \dot{x}_2(t)) = 0$   
with fixed-end-point conditions

$$\begin{aligned} x_1(t_0) &= x_{10}; & x_2(t_0) &= x_{20} \\ x_1(t_f) &= x_{1f}; & x_2(t_f) &= x_{2f} \end{aligned}$$

IT Roorkee    NPTEL ONLINE CERTIFICATION COURSE

We consider the extremization of the functional  $J$  which is the function of functions  $x_1(t)$  and  $x_2(t)$ , can be written as  $t_0$  to  $t_f$  integral  $V$  of  $x_1(t)$ ,  $x_2(t)$ ,  $\dot{x}_1(t)$ ,  $\dot{x}_2(t)$ ,  $t$ ,  $dt$ . So, objective is to find out the optimal value of this subjected to the condition  $J$  of  $x_1$ ,  $x_2$ ,  $\dot{x}_1$ ,  $\dot{x}_2$  equals to 0.

(Refer Slide Time: 01:39)

**Optimum of Functional with Conditions**

Form an *augmented* functional

$$J_a = \int_{t_0}^{t_f} \mathcal{L}(x_1(t), x_2(t), \dot{x}_1(t), \dot{x}_2(t), \lambda(t), t) dt$$

$\lambda(t)$  is the Lagrange multiplier, and the Lagrangian  $\mathcal{L}$ , is defined as

$$\begin{aligned} \mathcal{L} &= \mathcal{L}(x_1(t), x_2(t), \dot{x}_1(t), \dot{x}_2(t), \lambda(t), t) \\ &= V(x_1(t), x_2(t), \dot{x}_1(t), \dot{x}_2(t), t) \\ &\quad + \lambda(t)g(x_1(t), x_2(t), \dot{x}_1(t), \dot{x}_2(t)) \end{aligned}$$

 IIT ROORKEE  NFTEL ONLINE CERTIFICATION COURSE

So, for this case, we will consider the fix endpoint problem in which my initial condition for the  $x_1$  and  $x_2$  are given, similarly the final condition for the  $x_1$  and the  $x_2$  are given. So, this problem we will use a Lagrangian approach, first we will define the augmented function  $J$  which is nothing, but the Lagrangian which can be defined as  $V$  plus  $\lambda g$ . So, if we define the Lagrangian  $L$  as  $V$  plus  $\lambda g$ .

So, we can define our augmented functional as  $\int_{t_0}^{t_f} L dt$ . Here  $L$  is a function of  $x_1, x_2, \dot{x}_1, \dot{x}_2, \lambda, t$ . Say as our main problem was to minimization of the  $J$ , if you will see the minimization of the  $J$  this is nothing, but the minimization of  $J$  because  $L$  we are defining as  $V$  plus  $\lambda g$ , and this  $g$  is nothing but 0. So, if I am minimizing the  $J$  again I am minimizing the  $V$  as a integrants; from  $t_0$  to  $t_f$  where you place here take  $g$  as a 0. So, this is nothing, but by  $V dt$  which is similar to my functional  $J$ . So, the minimization of the  $J$  or the minimization of the  $J$  will give me the same results.

(Refer Slide Time: 03:04)

## Optimum of Functional with Conditions

Assume optimal values and then consider the *variations* and *increment* as

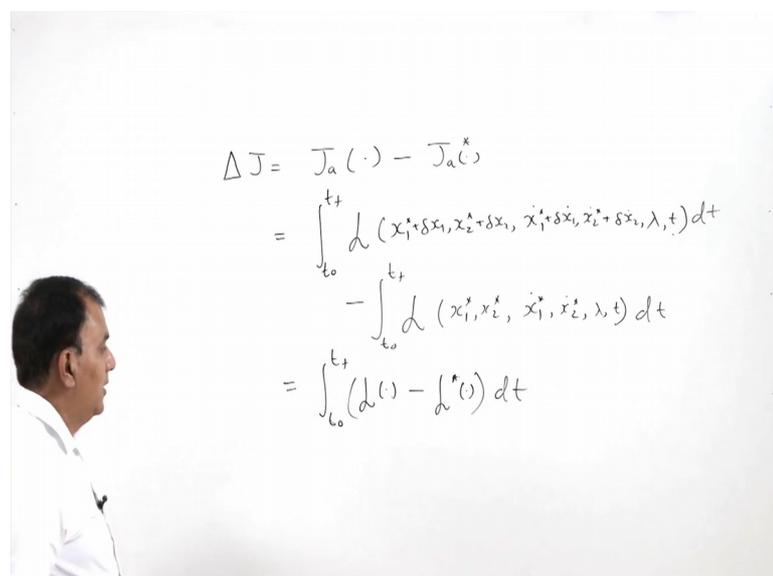

$$x_i(t) = x_i^*(t) + \delta x_i(t), \quad \dot{x}_i(t) = \dot{x}_i^*(t) + \delta \dot{x}_i(t), \quad i = 1, 2$$

$$\Delta J_a = J_a(x_i^*(t) + \delta x_i(t), \dot{x}_i^*(t) + \delta \dot{x}_i(t), t) - J_a(x_i^*(t), \dot{x}_i^*(t), t)$$

So, please start our problem first we consider the optimum value for  $x_1$  and  $x_2$  say  $x_1^*$  and  $x_2^*$ . If there is a variation of  $\delta x_1$  and  $\delta x_2$  in this so, at a variation point I can write my  $x_1$  as  $x_1^* + \delta x_1$ ,  $x_2$  as  $x_2^* + \delta x_2$  similarly  $\dot{x}_1$  as  $\dot{x}_1^* + \delta \dot{x}_1$ ,  $\dot{x}_2$  as  $\dot{x}_2^* + \delta \dot{x}_2$ . With these variation point I define my  $J$  similarly at the optimal point I define my  $J^*$ , the difference of these 2 is giving me nothing but the increment.

So, increment I can write as  $\Delta J$  equal to  $J$  at the point, at the variation point  $x$  plus  $\delta x$  minus  $J$  at the optimal point. So, these differences give me nothing, but my increment.

(Refer Slide Time: 04:24)

$$\begin{aligned}
 \Delta J &= J_a(\cdot) - J_a^* \\
 &= \int_{t_0}^{t_f} \mathcal{L}(x_1 + \delta x_1, x_2 + \delta x_2, \dot{x}_1 + \delta \dot{x}_1, \dot{x}_2 + \delta \dot{x}_2, \lambda, t) dt \\
 &\quad - \int_{t_0}^{t_f} \mathcal{L}(x_1^*, x_2^*, \dot{x}_1^*, \dot{x}_2^*, \lambda, t) dt \\
 &= \int_{t_0}^{t_f} (\mathcal{L}(\cdot) - \mathcal{L}^*(\cdot)) dt
 \end{aligned}$$

So, this increment if you will write some writing my delta J as, J minus J at optimal point, this I am writing as a star, and what is my J if I will see this J is nothing but my L integral of t 0 to t f L d t.

(Refer Slide Time: 04:54)

### Optimum of Functional with Conditions

Using the Taylor series expansion and retaining linear terms only, the first variation of the functional  $J_a$  becomes

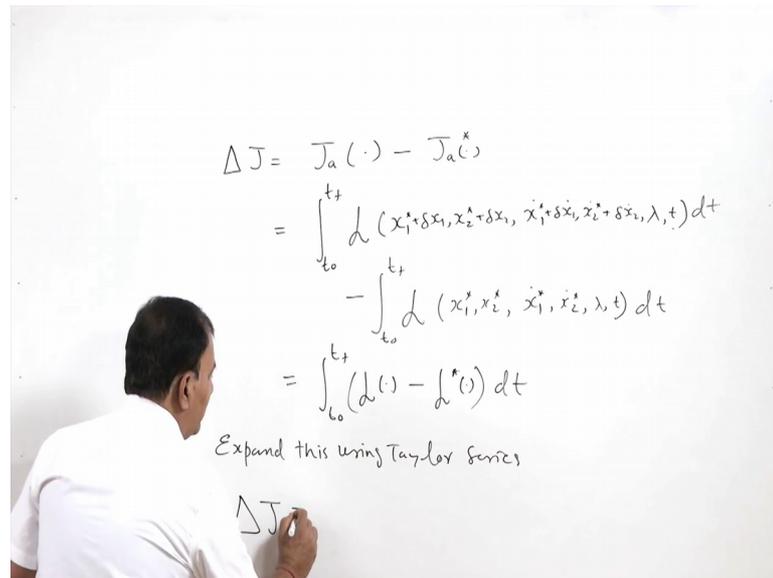

$$\delta J_a = \int_{t_0}^{t_f} \left[ \left( \frac{\partial \mathcal{L}}{\partial x_1} \right)_* \delta x_1(t) + \left( \frac{\partial \mathcal{L}}{\partial x_2} \right)_* \delta x_2(t) + \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* \delta \dot{x}_1(t) + \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_2} \right)_* \delta \dot{x}_2(t) \right] dt$$

So, I can write this is t 0 to t f L at the point, x 1 star plus delta x 1, x 2 star plus delta x 2, x 1 dot star plus delta x 1 dot x 2 dot star plus delta x 2 dot lambda and t. So, this is my J at variation point minus t 0 to t f, L at the optimal point which is nothing but my x 1 star, x 2 star, x 1 dot, x 2 dot, lambda and t d t and naturally this is also d t.

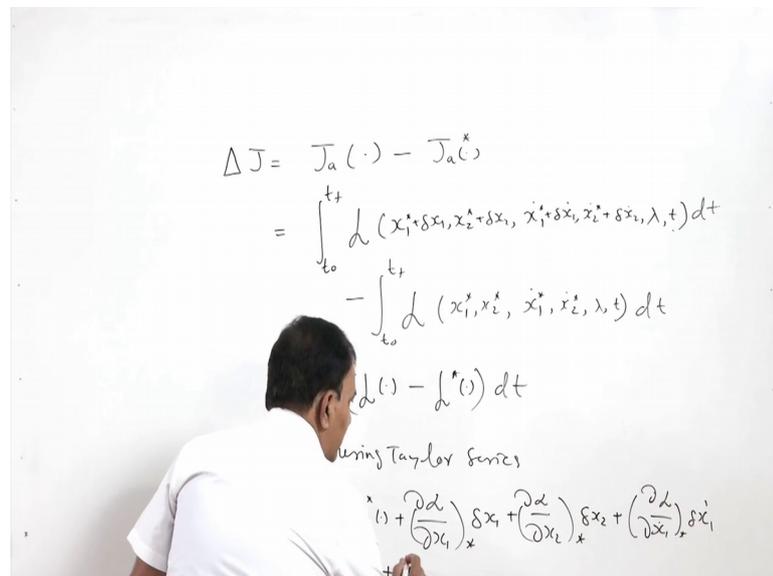

So, if I will write in a simple term this is nothing but t 0 to t f, L at variation point minus L at optimal point d t.

(Refer Slide Time: 06:47)

It will explain this by using Taylor series. So, what I will get? My delta J.

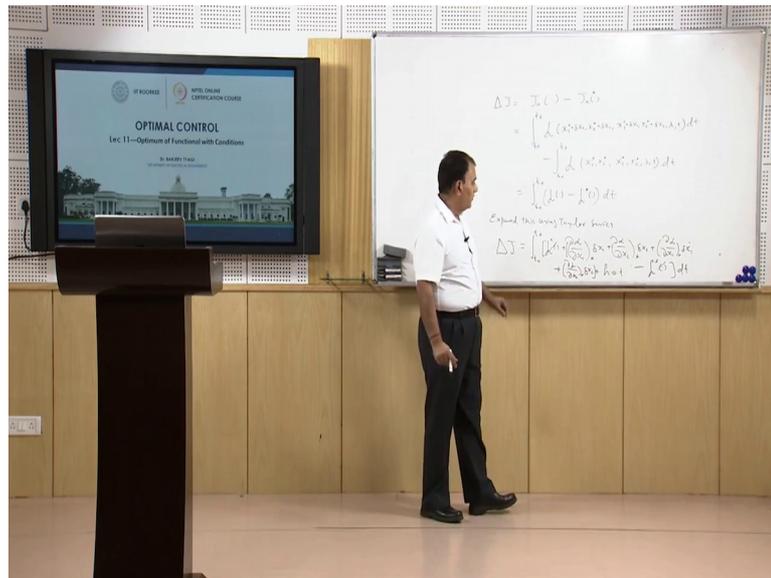

(Refer Slide Time: 07:11)

So, this is the same as we have done before nothing but t 0 to t f, L at optimal point plus del L by del x 1, delta x 1 del L by del x 2, delta x 2, and similarly for x 1 dot and x 2 dot, del L by del x 1 dot, delta x 1 dot plus del L by del x 2 dot, delta x 2 dot plus.

Now, I will get some higher order terms into d t; d t we can also include L star into this minus this L star into d t. So, this L star will cancelled out we are left with the first order term and the higher order term.

(Refer Slide Time: 08:30)

So, if we will write the first variation. So, first variation I can simply write as  $\delta L$  by  $\delta x_1$ ,  $\delta L$  by  $\delta x_2$ ,  $\delta L$  by  $\delta \dot{x}_1$ , plus  $\delta L$  by  $\delta \dot{x}_2$ . So, this means I am simply collecting my first order terms, because this  $L$  is canceled with this  $J$  I am getting up to this my first order term which will be nothing, but my first variation, higher order terms we are neglecting. So, my first variation is given by as given here.

Now, in this case we have coefficients of the  $\delta x_1$ ,  $\delta x_2$  and  $\delta \dot{x}_1$ ,  $\delta \dot{x}_2$ . So, if we will consider the third term  $\delta L$  by  $\delta \dot{x}_1$  using integration by parts I can convert my  $\delta \dot{x}_1$  into  $\delta x_1$ . So, we are considering the third term of this expression  $\delta L$  by  $\delta \dot{x}_1$ .

(Refer Slide Time: 10:03)

**Optimum of Functional with Conditions**

Using integration by parts,

$$\begin{aligned} \int_{t_0}^{t_f} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* \delta \dot{x}_1(t) dt &= \int_{t_0}^{t_f} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* \frac{d}{dt} (\delta x_1(t)) dt \\ &= \int_{t_0}^{t_f} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* d(\delta x_1(t)) \\ &= \left[ \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* \delta x_1(t) \right]_{t_0}^{t_f} \\ &\quad - \int_{t_0}^{t_f} \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* \delta x_1(t) dt \end{aligned}$$

 IIT ROORKEE
  NITEL ONLINE CERTIFICATION COURSE

So, integral of del L by del x 1 dot into delta x 1 dot d t.

(Refer Slide Time: 10:18)

$$\mathcal{L} = V_0 + \lambda g(\cdot)$$

$$\frac{\partial \mathcal{L}}{\partial \lambda} = g(\cdot) = 0$$

$$\int_{t_0}^{t_f} u dv = [uv]_{t_0}^{t_f} - \int_{t_0}^{t_f} v du$$

This we are integrating by parts using the same expression integral of as we have seen before u d v is nothing, but my u v, t 0 to t f is my integral limit is t 0 to t f, minus integral t 0 to t f, v d v.

So, if we will see here my u del L by del x 1 dot, and V is del x 1 dot we are writing as d by d t del x 1 t. So, I am taking d L by del x 1 dot as my u, del x 1 t as my V. So, if my expression will become this is my u d v, this u d v is u into v t 0 into t f as we have seen

here minus  $t_0$  to  $t_f$   $v$  and  $d u d \mathcal{L}$  by  $\delta x$  if  $t$  will cancelled out. So, my  $u$  is  $\delta \mathcal{L}$  by  $\delta x \dot{}$ . So, this is my  $u$ , so  $d$  of  $u$ . So, this means the third term which we have taken as  $\delta \mathcal{L}$  by  $\delta x_1 \dot{}$ ,  $\delta x_1 \dot{}$   $t$  this can be written as  $\delta \mathcal{L}$  by  $\delta x_1 \dot{}$ ,  $\delta x_1 \dot{}$   $t_0$  to  $t_f$ , minus integral of  $d$  by  $d t$   $\delta \mathcal{L}$  by  $\delta x_1 \dot{}$ ,  $\delta x_1 \dot{}$   $t d t$ .

Similarly, the last term here which is in terms of the  $\delta x_2 \dot{}$  can be expressed in terms of the  $\delta x_2$ . So, if we will substitute the value of third term and the fourth term in terms of the  $\delta x_1$  and  $\delta x_2$ .

(Refer Slide Time: 12:27)

### Optimum of Functional with Conditions

Using the above, we have the first variation

$$\begin{aligned} \delta J_a = & \int_{t_0}^{t_f} \left[ \left( \frac{\partial \mathcal{L}}{\partial x_1} \right)_* \delta x_1(t) + \left( \frac{\partial \mathcal{L}}{\partial x_2} \right)_* \delta x_2(t) \right] dt \\ & + \left[ \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* \delta x_1(t) \right]_{t_0}^{t_f} + \left[ \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_2} \right)_* \delta x_2(t) \right]_{t_0}^{t_f} \\ & - \int_{t_0}^{t_f} \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* \delta x_1(t) dt - \int_{t_0}^{t_f} \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_2} \right)_* \delta x_2(t) dt \end{aligned}$$

IIT ROORKEE

NPTEL ONLINE  
CERTIFICATION COURSE

So, we will get our expression as  $\delta J$ . So, my; these 2 terms representing the third term and these 2 terms are representing my last term. If the boundary conditions are considered this means  $t_0$  to  $t_f$ , if I will place in this, this is nothing but  $\delta x_1$  of  $t_f$ ,  $\delta x_1$  of  $t_0$ ,  $\delta x_2$  of  $t_f$   $\delta x_2$  of  $t_0$  and what we have considered; this all conditions I am given with as we can see in my problem  $x_1 t_0$ ,  $x_2 t_0$  are given,  $x_1 t_f$  and  $x_2 t_f$  are given.

(Refer Slide Time: 13:00)

**Optimum of Functional with Conditions**

The end points are

$$\delta x_1(t_0) = \delta x_2(t_0) = \delta x_1(t_f) = \delta x_2(t_f) = 0.$$

Therefore the first variation is

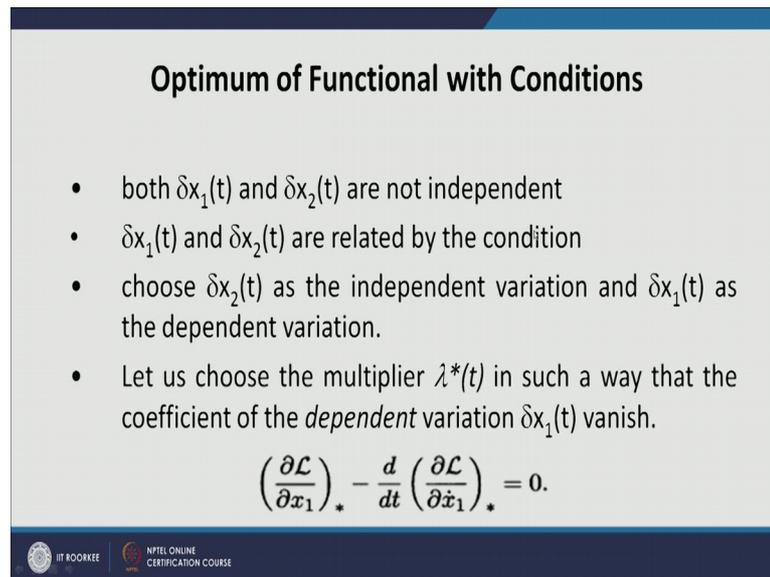

$$\delta J_a = \int_{t_0}^{t_f} \left[ \left( \frac{\partial \mathcal{L}}{\partial x_1} \right)_* - \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* \right] \delta x_1(t) dt + \int_{t_0}^{t_f} \left[ \left( \frac{\partial \mathcal{L}}{\partial x_2} \right)_* - \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_2} \right)_* \right] \delta x_2(t) dt.$$

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

So, this means my delta x 1 at t 0 delta x 2 at t 0, delta x 1 at t f, delta x 2 at t f this all values nothing, but will be 0.

So, in this what is by limiting terms? This time will become 0 and I am left with the del L by del x 1 minus d by d t, del L by del x 1 dot delta x 1 dot, del L by del x 2 minus d by d t del L by del x 2 dot delta x 2. And if you will say this will have nothing, but the structure of my Euler equation. So, like in the previous case we have taken as the coefficient of the delta x 1 to 0 and delta x 2 to 0, in this case because x 1 and x 2 are dependent variable they are not independent. So, we cannot read this as already we have discussed in the previous class, because these 2 are dependent. So, this means delta x 1 and delta x 2 will also be the dependent variable.

(Refer Slide Time: 14:23)

**Optimum of Functional with Conditions**

- both  $\delta x_1(t)$  and  $\delta x_2(t)$  are not independent
- $\delta x_1(t)$  and  $\delta x_2(t)$  are related by the condition
- choose  $\delta x_2(t)$  as the independent variation and  $\delta x_1(t)$  as the dependent variation.
- Let us choose the multiplier  $\lambda^*(t)$  in such a way that the coefficient of the *dependent* variation  $\delta x_1(t)$  vanish.

$$\left(\frac{\partial \mathcal{L}}{\partial x_1}\right)_* - \frac{d}{dt} \left(\frac{\partial \mathcal{L}}{\partial \dot{x}_1}\right)_* = 0.$$

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE

So,  $\delta x_1$  and  $\delta x_2$  are not independent they are related with a condition. So, what we can do? We can choose one of the variable as the independent variable and other as the dependent variable. So, in this case we are treating  $\delta x_2$  as my independent any variable I can treat as independent and other as the dependent. So, if  $\delta x_2$  is independent then  $\delta x_1$  will be the dependent variable. As previously we have seen in the Lagrangian approach Lagrangian multiplier  $\lambda$  we have to select. We can select a  $\lambda$  such that the coefficient of the dependent variable will 0, means we have taken  $x_2$  as the independent  $x_1$  as the dependent variable and if you will see if a function of  $\lambda$ . So, we can choose a  $\lambda$  which is making the coefficient of  $\delta x_1$  which is nothing, but my  $\frac{\partial \mathcal{L}}{\partial x_1} - \frac{d}{dt} \frac{\partial \mathcal{L}}{\partial \dot{x}_1} = 0$ .

So, I am making this term equal to 0 by selecting a proper value of the  $\lambda$ , let us say this is  $\lambda^*$ . So, by selecting this  $\lambda^*$  as the  $\lambda^*$  coefficient of the  $\delta x_1$  is going to be 0. If this coefficient is 0 so I am left only with the  $\delta x_2$  term.

(Refer Slide Time: 16:11)

### Optimum of Functional with Conditions

Therefore, the first variation becomes

$$\int_{t_0}^{t_f} \left[ \left( \frac{\partial \mathcal{L}}{\partial x_2} \right)_* - \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_2} \right)_* \right] \delta x_2(t) dt = 0.$$

Using the fundamental lemma  $\left( \frac{\partial \mathcal{L}}{\partial x_2} \right)_* - \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_2} \right)_* = 0.$

from the Lagrangian  $\left( \frac{\partial \mathcal{L}}{\partial \lambda} \right)_* = 0$

So, now,  $\delta x_2$  is independent and  $\delta x_2$  is also arbitrary. So, the coefficient of this also must be 0 this is our fundamental lemma which we have discussed before. So, due to the fundamental lemma I can write  $\left( \frac{\partial \mathcal{L}}{\partial x_2} \right)_* - \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_2} \right)_* = 0$ . And  $\mathcal{L}$  as already we have treated as  $V + \lambda g$ . So, if I will take  $\frac{\partial \mathcal{L}}{\partial \lambda}$  this is nothing, but my  $g$  and the condition already I have considered as 0.

(Refer Slide Time: 17:10)

### Optimum of Functional with Conditions

Combining the various relations the *necessary* conditions for extremization of the functional are

$$\begin{aligned} \left( \frac{\partial \mathcal{L}}{\partial x_1} \right)_* - \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_1} \right)_* &= 0 \\ \left( \frac{\partial \mathcal{L}}{\partial x_2} \right)_* - \frac{d}{dt} \left( \frac{\partial \mathcal{L}}{\partial \dot{x}_2} \right)_* &= 0 \\ \left( \frac{\partial \mathcal{L}}{\partial \lambda} \right)_* &= 0 \end{aligned}$$

So, this means my  $\frac{\partial L}{\partial \lambda}$  will also be 0. So, all this analysis basically lead to the necessary condition as  $\frac{\partial L}{\partial x_1} - \frac{d}{dt} \frac{\partial L}{\partial \dot{x}_1}$  is equal to 0, similarly  $\frac{\partial L}{\partial x_2} - \frac{d}{dt} \frac{\partial L}{\partial \dot{x}_2}$  equal to 0,  $\frac{\partial L}{\partial \lambda}$  also equal to 0. So, if you are finding the optimum of a value we can write this equation. As we can see here we have only 1 condition. So,  $\frac{\partial L}{\partial \lambda}$ . So, we have the three equations, and we are the three unknown  $x_1$ ,  $x_2$  and  $\lambda$ . So, these three equations will give us the three differential equations which simultaneously can be solved to determine the value of  $x_1$ ,  $x_2$  and  $\lambda$ , and these values at this point will be nothing, but my optimal values.

(Refer Slide Time: 18:25)

### Optimum of Functional with Conditions

For an nth order system  
Consider the extremization of a functional

$$J = \int_{t_0}^{t_f} V(\mathbf{x}(t), \dot{\mathbf{x}}(t), t) dt$$

$\mathbf{x}(t)$  is an nth order state vector  
subject to the condition

$$g_i(\mathbf{x}(t), \dot{\mathbf{x}}(t), t) = 0; \quad i = 1, 2, \dots, m$$

and boundary conditions,  $t_0, \mathbf{x}(t_0)$  and  $t_f, \mathbf{x}(t_f)$  are given

If we will journalize the relation so we can consider a nth order system in a way that  $J$  is my functional of  $V$   $x$ ,  $\dot{x}$  and  $t$  and here  $x$  is nothing but a nth order is state vector. So, this means we are considering my  $x$  as  $x_1, x_2, x_n$ . So, if we are seeing the  $V$   $x$  it is a  $V$   $x_1$  to  $x_n$  similarly  $\dot{x}_1$  to  $\dot{x}_n$  and  $t$ .

(Refer Slide Time: 19:13)

$$\begin{aligned}
 \mathcal{X} &= \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} \\
 V(x, \dot{x}, t) &= V(x_1, x_2, \dots, x_n, \dot{x}_1, \dot{x}_2, \dots, \dot{x}_n) \\
 m \text{ Conditions } &\begin{cases} g_1(x_1, x_2, \dots, x_n, \dot{x}_1, \dot{x}_2, \dots, \dot{x}_n) = 0 \\ \vdots \\ g_m(x_1, \dots, x_n, \dot{x}_1, \dots, \dot{x}_n) = 0 \end{cases}
 \end{aligned}$$

So, this means  $V(x, \dot{x}, t)$  is nothing, but my  $V(x_1, x_2, \dots, x_n, \dot{x}_1, \dot{x}_2, \dots, \dot{x}_n)$ . So, this is  $n$ th order state vector  $x$  we have considered here and this. So, our problem is to find out the optimal value of the  $J$ , which is subjected to the condition  $g_i(x, \dot{x}, t)$  where  $i$  is varying 1 to  $m$ , this means we have the  $m$  number of the condition. So, my condition is  $g_1(x_1, x_2, \dots, x_n, \dot{x}_1, \dot{x}_2, \dots, \dot{x}_n)$ , this must be equal to 0 and this is nothing, but  $g_1$  to  $g_m$  we are considering;  $x_1, x_2, \dots, x_n, \dot{x}_1, \dot{x}_2, \dots, \dot{x}_n$  and this must be equal to 0.

So, we have  $m$  condition, in the first case we have taken only the 2 variables  $x_1$  and  $x_2$  and 1 condition as the  $g$ . So, in general formulation of this problem we are considering the optimization of the  $J$ , which is subjected to  $m$  number of the conditions; and again we are considering my boundary conditions  $t_0$  and  $t_f$  are given.

(Refer Slide Time: 21:27)

**Optimum of Functional with Conditions**

Form an augmented functional

$$J_a = \int_{t_0}^{t_f} \mathcal{L}(\mathbf{x}(t), \dot{\mathbf{x}}(t), \boldsymbol{\lambda}(t), t) dt$$
$$\mathcal{L}(\mathbf{x}(t), \dot{\mathbf{x}}(t), \boldsymbol{\lambda}(t), t) = V(\mathbf{x}(t), \dot{\mathbf{x}}(t), t) + \boldsymbol{\lambda}'(t) \mathbf{g}_i(\mathbf{x}(t), \dot{\mathbf{x}}(t), t)$$

IIT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE

So, again this is a fixed endpoint problem as we have considering the previous case. So, this fixed endpoint problem can be journalized in the form that first we will write a J which is nothing, but the Lagrangian times d t, and Lagrangian is define nothing but as my V plus lambda prime g. Why lambda prime because for the m condition we have the m number of the Lagrangian multiplier.

(Refer Slide Time: 22:02)

Handwritten derivation showing the augmented Lagrangian  $L$  and the augmented functional  $J_a$ :

$$L = V(\cdot) + \lambda' g(\cdot)$$
$$= V(\cdot) + [\lambda_1, \lambda_2, \dots, \lambda_m] \begin{bmatrix} g_1(\cdot) \\ g_2(\cdot) \\ \vdots \\ g_m(\cdot) \end{bmatrix}$$
$$= V(\cdot) + \lambda_1 g_1(\cdot) + \lambda_2 g_2(\cdot) + \dots + \lambda_m g_m(\cdot)$$
$$J_a = \int_{t_0}^{t_f} L(\cdot) dt$$

So, if you will see what actually will be my Lagrangian and we are writing as V plus lambda prime g. G is a vector now or we are writing this as V plus lambda 1, lambda 2,

lambda m as g 1, g 2 and g m. So, my Lagrangian is nothing, but V plus lambda 1, g 1, plus lambda 2, g 2, and lambda m, g m. So, this is my Lagrangian. And what we are seeing my augmented function will be t 0 to t f, L d t because all my g sorry this is g 1, g 2, gm all my g 1 equal to 0, g 2 equal to 0, g m equal to 0. So, L minimization of the L is same as the minimization of the V.

So, the J which we have considered either I will take the minimization of the J or the minimizations of the J both are the similar as we already have discussed, and if you will follow the same approach.

(Refer Slide Time: 23:50)

**Optimum of Functional with Conditions**

The Euler-Lagrange equation on  $J_a$

$$\left(\frac{\partial \mathcal{L}}{\partial \mathbf{x}}\right)_* - \frac{d}{dt} \left(\frac{\partial \mathcal{L}}{\partial \dot{\mathbf{x}}}\right)_* = 0$$

$$\left(\frac{\partial \mathcal{L}}{\partial \lambda}\right)_* = 0$$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE

We will lead to the m number of the Euler equations which is del x by del x minus d by d t del L by del x dot equal to 0, and the m number of my condition equation which is del L by del lambda equal to 0; as del L by del lambda giving me the g. So, if we will see we have the total n plus m number of the equations. So, what the first equation giving me del L by del x minus d by d t del L by del x dot, because all the n number of the state.

(Refer Slide Time: 24:25)

$$n \text{ eqns } \left\{ \begin{array}{l} \left( \frac{\partial L}{\partial x_n} \right) - \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{x}_n} \right) = 0 \\ \vdots \\ \left( \frac{\partial L}{\partial x_1} \right) - \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{x}_1} \right) = 0 \end{array} \right.$$

$$m \text{ eqns } \left\{ \begin{array}{l} \left( \frac{\partial L}{\partial \lambda_1} \right) = 0 \\ \vdots \\ \left( \frac{\partial L}{\partial \lambda_m} \right) = 0 \end{array} \right.$$
 Total  $n+m$  eqns

So, this is nothing, but  $\frac{\partial L}{\partial x}$  minus  $\frac{\partial L}{\partial \dot{x}}$  by  $\frac{d}{dt}$ ,  $\frac{\partial L}{\partial x_1}$  minus  $\frac{\partial L}{\partial \dot{x}_1}$  by  $\frac{d}{dt}$ , and these we are finding for optimal condition, this must be equal to 0 and similarly my  $n$ th equation is  $\frac{\partial L}{\partial x_n}$  minus  $\frac{d}{dt}$   $\frac{\partial L}{\partial \dot{x}_n}$  that must be equal to 0 and the conditional equations are  $\frac{\partial L}{\partial \lambda_1}$  this means this is nothing, but my  $\frac{\partial L}{\partial \lambda_1}$  is 0 up to  $\frac{\partial L}{\partial \lambda_m}$  equals to 0.

So, these are  $n$  equations and these are  $m$  equations. So, my total  $n$  plus  $m$  equation I have. So, total  $n$  plus  $m$  equations we have, and number of variables are  $x_1$  to  $x_n$  and  $\lambda_1$  to  $\lambda_m$ ; so total  $n$  plus  $m$  variable,  $n$  plus  $m$  equations which can be solved to determine the all my  $x_1$  and  $\lambda$ . So, as we have seen that we have  $n$  number of the equations given by Euler equation here, and the  $m$  number of my condition equation.

**Optimum of Functional with Conditions**

Example:  
Minimize the PI  $J = \int_0^1 [x^2(t) + u^2(t)] dt$

With boundary conditions  $x(0) = 1; x(1) = 0$

Subjected to the condition  $\dot{x}(t) = -x(t) + u(t)$

IIT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE

So, next we will take one example and see how this knowledge can be implemented to determine the different variables. My problem here is I have to minimize the J which is 0 to 1 x square t plus u square t d t, subjected to the boundary condition x 0 equal to 1 x 1 equal to 0, and my condition given here is the x dot as minus x t plus u t.

So, means we have to minimize the J subjected to this condition. So, what I have in the integrant x square plus u square this is nothing but my V, and last equation nothing, but giving me the condition.

(Refer Slide Time: 27:33)

$$V = x^2(t) + u^2(t)$$
$$\dot{x}(t) = -x(t) + u(t)$$
$$g = \dot{x}(t) + x(t) - u(t) = 0$$

Define Lagrangian  $L = V + \lambda f$ 
$$= x^2 + u^2 + \lambda(\dot{x} + x - u)$$

Euler Eqn  $\frac{\partial L}{\partial x} - \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{x}} \right) = 0$ 
$$2x + \lambda - \frac{d}{dt}(\lambda) = 0$$
$$2x + \lambda - \dot{\lambda} = 0 \longrightarrow \textcircled{1}$$

So, if I will write all variables on one side I can write this as my g. This means we have the V as given here  $x^2 + u^2$ , V is  $x^2 + u^2$ , and the condition given here is  $\dot{x} - x + u = 0$ , this can be written as  $\dot{x} + x - u = 0$ , and this I can take it as my g. So, my first step is to define the Lagrangian L as V plus lambda f, which is nothing but my  $x^2 + u^2 + \lambda(\dot{x} + x - u)$ . So, this is my Lagrangian and what we have to do, we have to now write my Euler-Lagrange equation and the condition equation.

So, if I will write my Euler equation as  $\frac{\partial L}{\partial u} - \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{u}} \right) = 0$ . So,  $\frac{\partial L}{\partial u}$  will be what. So, this is  $2u - \lambda$ . So, this is  $2u - \lambda = 0 \Rightarrow u = \frac{1}{2}\lambda$ . So, this is  $\frac{\partial L}{\partial \lambda} = 0 \Rightarrow \dot{x} + x - u = 0$ . So, this is  $2x + \lambda - \lambda = 0$ , I say this is my note down equation 1.

(Refer Slide Time: 30:54)

Handwritten mathematical derivation showing the steps to solve the Euler-Lagrange equations for the given problem:

$$\frac{\partial L}{\partial u} - \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{u}} \right) = 0$$

$$2u - \lambda = 0 \Rightarrow u = \frac{1}{2}\lambda \rightarrow \textcircled{2}$$

$$\frac{\partial L}{\partial \lambda} = 0 \Rightarrow \dot{x} + x - u = 0 \rightarrow \textcircled{3}$$

From eqn (2)  $x + x - \frac{1}{2}\lambda = 0 \Rightarrow \lambda = 2(x + \dot{x})$

From (1)  $2x + 2(\dot{x} + x) - 2(\ddot{x} + \dot{x}) = 0$

$$\ddot{x} - 2x = 0$$

Solution of the differential eqn

$$x^*(t) = C_1 e^{-\sqrt{2}t} + C_2 e^{\sqrt{2}t}$$

$x(0) = 1$   
 $C_1 + C_2 = 1 \rightarrow \textcircled{4}$   
 $x(1) = 0$   
 $C_1 e^{-\sqrt{2}} + C_2 e^{\sqrt{2}} = 0 \rightarrow \textcircled{5}$   
 $\textcircled{4}$  &  $\textcircled{5}$  Solve for  $C_1$  &  $C_2$

My next Euler equation will be my another variable is  $\frac{\partial L}{\partial \dot{u}} - \frac{d}{dt} \left( \frac{\partial L}{\partial \ddot{u}} \right) = 0$ . We know my; what is my L if I will write this. So, this gives me nothing but  $2u - \lambda = 0$ , this means I can write my optimal u as  $\frac{1}{2}\lambda$ . And my condition equation is  $\frac{\partial L}{\partial \lambda} = 0$  with given value of L my this equation comes out to be nothing, but what my condition is  $\dot{x} + x - u = 0$ .

I say this is my equation 2 this is my equation 3. So, as a three equations equation number 1  $2x + \lambda - \dot{\lambda} = 0$ , second equation as my  $u$  star as  $\frac{1}{2}\lambda$ , and the third equation  $\dot{x} + x - u = 0$ . So, these three equation I have to solve simultaneously to determine the value of the  $x$  star  $t$ ,  $u$  star  $t$ , and  $\lambda$   $t$ . So, simple way to solve this equation I have  $u$  star as  $\frac{1}{2}\lambda$  I place. So, from equation three what we can write  $\dot{x} + x - \frac{1}{2}\lambda = 0$ , this implies my  $\lambda$  is nothing but  $2\dot{x} + 2x$ , as  $\lambda$  is  $x$  plus sorry  $2\dot{x} + 2x$  and my equation number 1 is  $2x + \lambda - \dot{\lambda}$ . So, I place into now from 1 what we can write?  $2x + \lambda$  in place of  $\lambda$  I write  $2x + 2\dot{x} + 2x$ , minus  $\dot{\lambda}$  means I am taking the derivative of this  $2x + 2\dot{x} + 2x$  dot equals to 0.

So, if I will simplify this I will simply get  $x'' - 2x = 0$ . So, the solution of this differential equation is we can write as  $x(t) = C_1 e^{-\sqrt{2}t} + C_2 e^{\sqrt{2}t}$ . Now this  $C_1$  and  $C_2$  we can find out using the terminal conditions which is  $x(0) = 1$  and  $x'(0) = 0$ . So, I have  $x(0) = 1$  this means the  $t = 0$   $x(0)$  is 1. So, what I will have?  $C_1 + C_2 = 1$  and my another condition is  $x'(0) = 0$  where  $t$  is 0. So, this is  $C_1 e^{-\sqrt{2} \cdot 0} + C_2 e^{\sqrt{2} \cdot 0} = 1$  that is 0.

So, 1 2 3 I can say this is my 4 this is my 5 equation 4 and f5 you solve this four solve for  $C_1$  and  $C_2$ . So, if we will solve this for  $C_1$  and  $C_2$  we get.

(Refer Slide Time: 37:03)

$$C_1 = \frac{1}{(1 - e^{-2\sqrt{2}})}; \quad C_2 = \frac{1}{(1 - e^{2\sqrt{2}})}$$

$$U^*(t) = \frac{1}{2} \lambda(t) = x + \dot{x}$$

$$\lambda(t) = 2(\dot{x} + x)$$

$$U^* = C_1(1 - \sqrt{2})e^{-\sqrt{2}t} + C_2(1 + \sqrt{2})e^{\sqrt{2}t}$$

$\dot{x} - 2x = 0$

Solution of the differential eqn

$$x^*(t) = C_1 e^{-\sqrt{2}t} + C_2 e^{\sqrt{2}t}$$

$x(0) = 1$   
 $C_1 + C_2 = 1 \rightarrow (4)$   
 $x(1) = 0$   
 $C_1 e^{-\sqrt{2}} + C_2 e^{\sqrt{2}} = 0 \rightarrow (5)$   
 $(4) \& (5)$  Solve for  $C_1$  &  $C_2$

$C_1$  as  $\frac{1}{1 - e^{-2\sqrt{2}}}$  and  $C_2$  as  $\frac{1}{1 - e^{2\sqrt{2}}}$ . So, if you know  $C_1$  and  $C_2$  we can also write what is my  $u^*(t)$ , which is nothing but  $\frac{1}{2} \lambda(t)$ , sorry first we have to find out  $\lambda(t)$  which is nothing, but my  $\dot{x} + x$ .

So, this is sorry  $\lambda(t)$  is twice of  $\dot{x} + x$ . So, if I am writing  $u(t)$  this is nothing, but  $\dot{x} + x$ , I know; what is my  $x(t)$ ? So, I have  $\dot{x}$  and  $x$  if I will write. So, this will give me  $C_1 \frac{1}{1 - \sqrt{2}} e^{-\sqrt{2}t} + C_2 \frac{1}{1 + \sqrt{2}} e^{\sqrt{2}t}$ . So, this will be my  $u^*$ , and  $\lambda^*$  can directly be written by this. So, all 3,  $x$ ,  $x^*$  and  $\lambda^*$  all the values can be determined utilizing my necessary condition  $\frac{\partial L}{\partial x} - \frac{d}{dt} \frac{\partial L}{\partial \dot{x}} = 0$  which is nothing, but my Euler equation, my 2 variables are  $x$  and  $u$  which is given here  $x$  and  $u$  are my 2 variables. So, has the 2 equations as  $\frac{\partial L}{\partial x}$ ,  $\frac{\partial L}{\partial u}$ , and the third will be  $\frac{\partial L}{\partial \lambda}$ .

So, these can be solved to determine my all the variables; if everything is known then directly with the value of the  $x(t)$  optimal value of  $x$  and  $u$ , I can find out what will be my minimum value of the  $J$ .

So, in this class we have discussed about the optimal value of a functional with given condition, in the next class we will apply our apply this concept to a optimal control problem. So, today I stop here.

Thank you very much.
