Lecture No. # 18

Welcome viewers to the NPTEL lecture series on the calculus of variations. This is the 18th lecture of the series. We recall that in the last lecture, we started with sufficient conditions on the integrand of the functional, which we have been considering. And we obtained Jacobi's equation, which ensures that we have central field at the point a of the extremal, and that extremal which we are testing whether it gives us the optimal value of the functional, we would like to see that the point b is within the central field. That means around d the extremals do not intersect. So, that is the condition, which is known as Jacobi's condition.

(Refer Slide Time: 01:13)

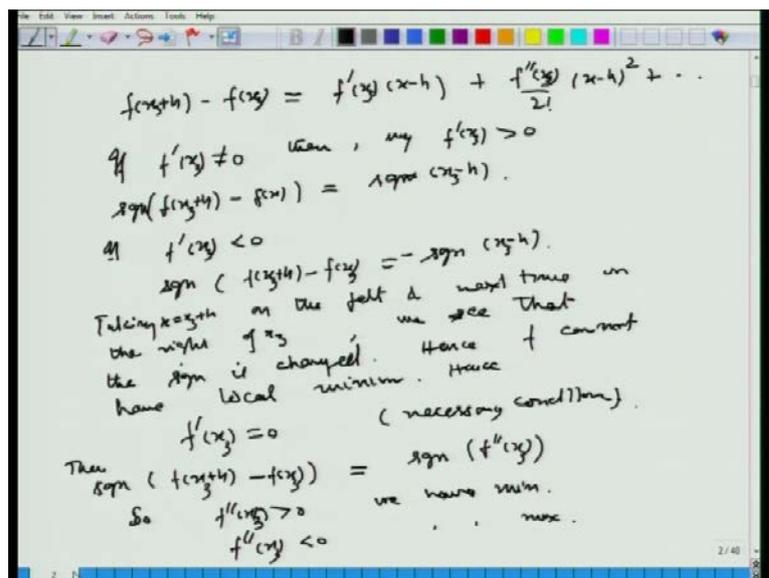

So, we started in the last lecture with the brief introduction to the notion of minima-maxima of a function, where we consider, the case where the function f is defined on the interval x_1 to x_2 into \mathbb{R} , sufficiently smooth, so that whatever derivatives we are considering on f are continuous. So, we can expand this $f(x)$ in any at any interior point

x in the interval x_1 to x_2 . So, we considered this point x_3 here. So, supposing we expand this around x_3 like this. So, all the derivatives will be evaluated at x_3 . So, f of x_3 plus h would can be written as f of x_3 plus f prime x_3 into x_3 minus h and f double prime at x_3 upon factor $2 \times x_3$ minus h square and so on.

So, here if we have minimum at this point x_3 , which is an interior point of the interval then we can see that around this point, this is the like you have cup kind of a figure here. And similarly, if x at x_3 which is an interior point of the interval x_1, x_2 , if at that point, if the local maximum is there, then we have this inverted cup kind of a thing, shape of the curve around this x_3 . So, we can see that in the neighboring point here, f in the case of minimum at x_3 , f at x_3 plus h , where h is small, may be positive or negative. If it is positive, we are on the right of x_3 . If h is negative, we are in of left of the x_3 . And so, those values should have been more than the value at f of x_3 . So, here we have f of x_3 greater than equal to f of x must be greater than equal to f of x_3 , for any x in small neighborhood around this x ; that is x_3 minus epsilon to x_3 plus epsilon.

Similarly, here f of x around this x_3 must be the more than, f of x must be a less than the value at f of x_3 , which should be the maximum in the neighborhood around this endpoint x_3 that is x_3 minus epsilon to x_3 plus epsilon, in case of maximum at x_3 .

(Refer Slide Time: 03:52)

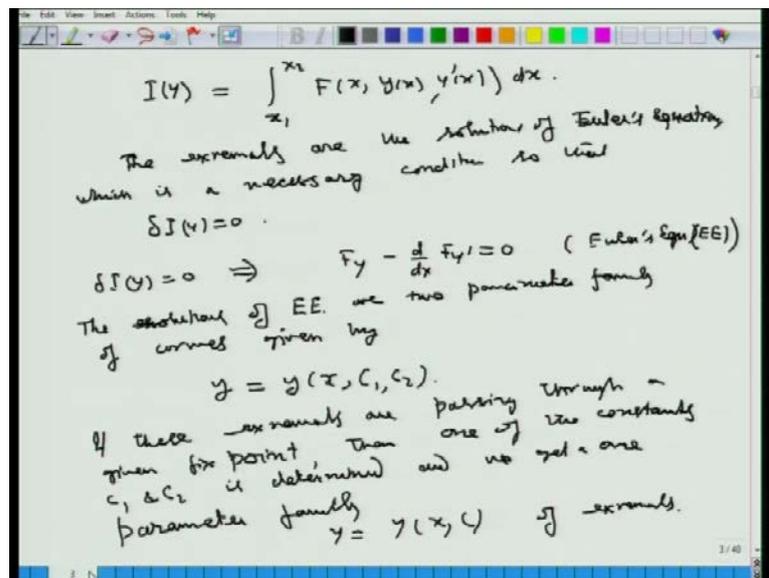

So, if you look at the expansion f of x_3 plus h minus f of x_3 , which is a prime at x_3 , x_3 minus h plus f double prime at x_3 upon factor $2 \times x_3$ minus h whole square and so on.

Then, we see that this left hand side should have same sign in the neighborhood of x_3 . So, therefore, if this prime x_3 is not 0, we see that this term, for a small h , this is the dominating term and the sign of the left hand side will be actually sign of the first term on the right hand side. And therefore, if prime at x_3 is not 0, it changes sign, and therefore, **which** then the condition of minimality or maximality at x_3 is violated.

So, the necessary condition is that a prime **attacks** x_3 must be 0, and then we see this sign of this left hand side equal to the sign of the next term, non-zero term, if a double prime at x_3 is not 0, then we see that since x_3 minus h square is coming, which is always non negative here. So, the sign of left hand side will be determined by a sign of f double prime at x_3 for small values of h . And so we see that the testing of the sufficient conditions for the minima or maxima at x_3 are given by that f double derivative a prime **f double prime** at x_3 , if it is positive, then we see that we get minimum at x_3 , if f double prime at x_3 is negative, then we get maximum.

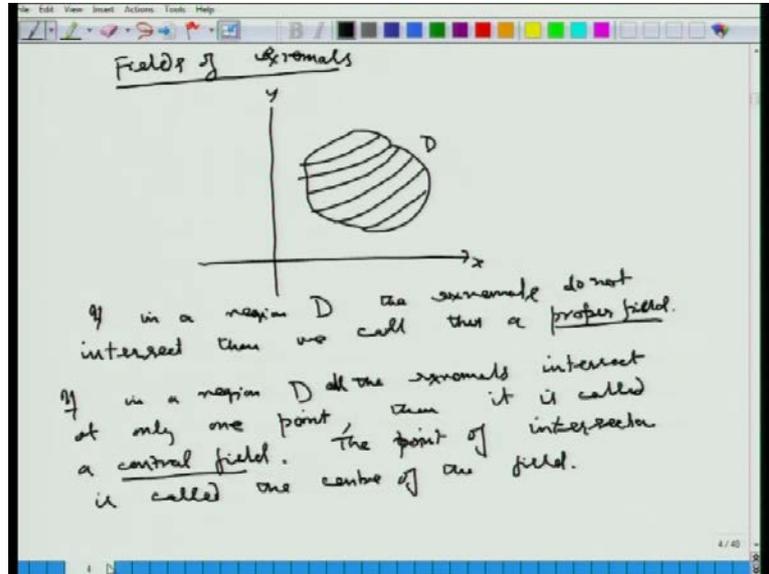

(Refer Slide Time: 05:37)

So, the similar concept we would be actually establishing for the functional. So, here a prime at x_3 , it being 0 is equivalent to in the case of functional, that the first variation that is **delta** small delta I is 0, which we had got earlier and this condition implies that F_y minus d by dx $F_{y'}$ equal to 0 that is Euler's equation is the necessary condition here, and so solving that equation, because the **second order equation** second order ordinary differential equation in y , so it will have solution involving two arbitrary

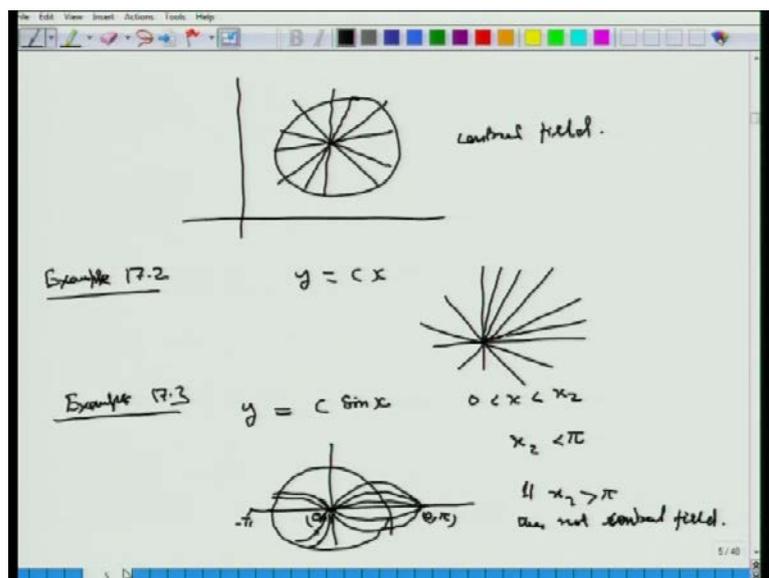

constants. And if we see that the point is fixed, then we can determine one of these two constants, and then, we get to one parameters of family of the extremals.

(Refer Slide Time: 06:30)

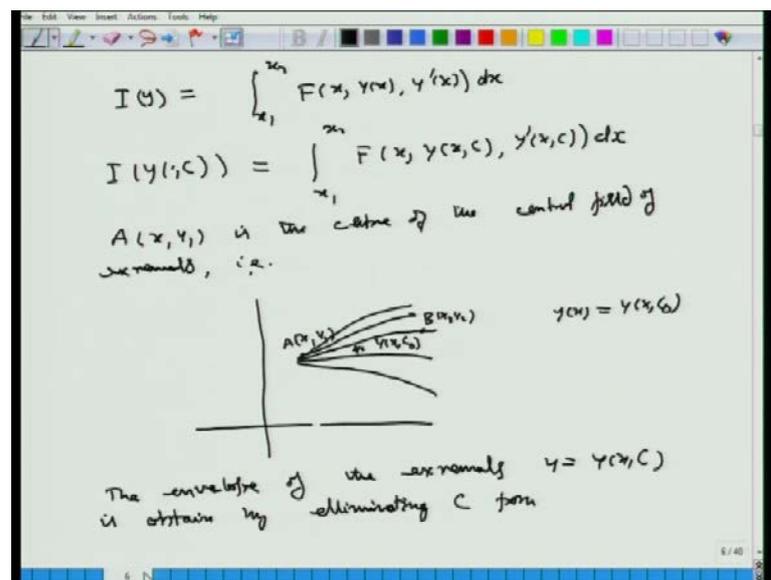

And then we defined the concept of fields, various fields. Here, if the extremals in region D do not intersect at all, such a field is called proper field. And if they intersect at one point and nowhere else, then it is called central field, and the point where all these extremals intersect is called the centre of the field.

(Refer Slide Time: 06:45)

And we had consider these examples like, y equal to $C \sin x$, here at the origin that all the extremals here, all the curves intersect here, and then next they intersect like 0π on the right or $0 \text{ minus } \pi$ on the left. And so, if we have this small neighborhood around 0 , then in that it is a central field provided π or $\text{minus } \pi$ are not there, 0π or $0 \text{ minus } \pi$ are not there in the domain. So, it forms a central field in the small neighborhood around 0 , the origin.

(Refer Slide Time: 07:39)

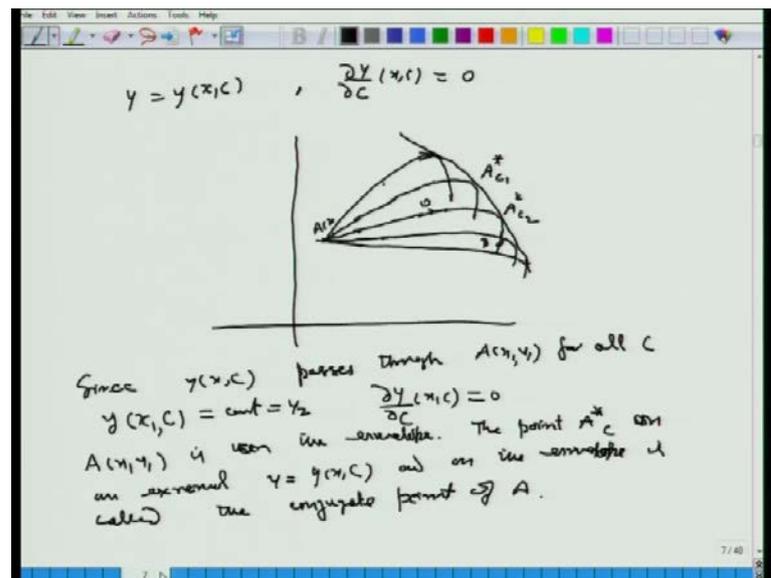

Now, we considered the functional $I(y)$, which is x_1 to x_2 F of x, y, y' dx , and we consider, it is values only on extremals like we solved this equation here. In this case, in the function case, we solve this f' at x_3 is equal to 0 , so all those x_3 , we satisfy this are called critical point. So, here like that they are called extremals, which are satisfying Euler's equation. And so, we have taken that the point A is fixed. So, all these extremals are passing through this point. And we are looking for that extremal here for on which this functional has optimal value, whether minimum or maximum, **will** we will be the getting certain conditions, sufficient conditions to determined, whether $I(y)$ is having maximum value or minimum value.

So, we considered here this family and we want to see that this given extremal whether this, which is $y(x)$ equal to $y(x, c_0)$. So, c_0 is a fixed constant **parameter** value of the parameter c . So that this A the extremal passing through A and B , whether it optimizes or not that is what we would like to see.

So, here first thing is that like that point x_3 was an interior point. Similarly, here this extremal should be an interior extremal that on the left side or right side or above or below of **this functional** this extremal there should be other extremals as well. So, this extremal should not be the boundary of the region. So that is one condition, which is required.

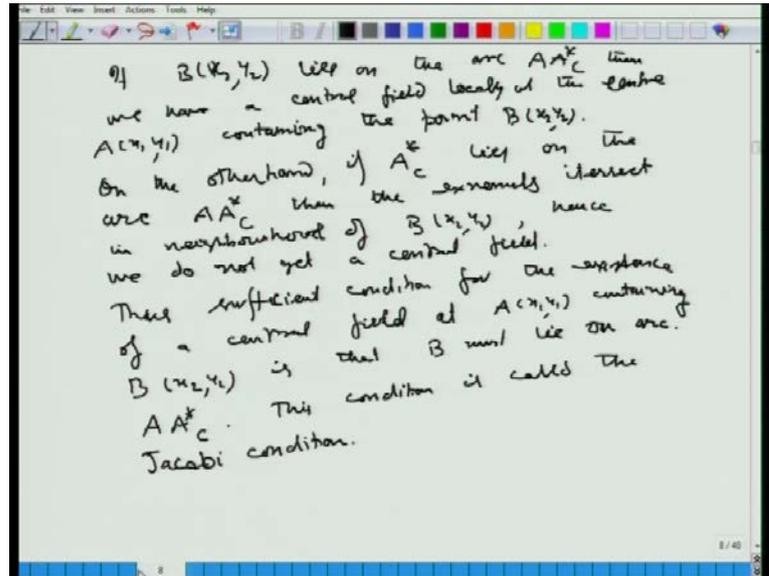

(Refer Slide Time: 09:36)

And then, we solve this y equal to $y(x, c)$ and $\frac{\partial y}{\partial c}(x, c)$ to get this c ; it is called c discriminant curve. So, we find this c discriminant curve. So, that includes this point $A(x_1, y_1)$, because here we have seen that at x_1 , this y of x_1 , because it is on the extremal. So, it satisfies and $\frac{\partial y}{\partial c}$, because all the extremals are passing through that. So, it is a fix number y_2 and therefore, $\frac{\partial y}{\partial c}(x_1, c)$ will be 0.

So, A is there on that c discriminant curve and the **envelope of this family of $y(x)$** envelope of the family of these extremals is also c discriminant curve, and the picture is like this, here we take various extremals. And the points, which are there on the extremal like one A is there, and then another one, which is there on the extremal as well as on the envelope that we denoted the conjugate point of A . It is denoted as $A^*_{c_1}$ like c is taking various values. So, we get different extremals. So, correspondingly we get a point on the envelope. And so that is called, so $A^*_{c_1}$ is called the conjugate of A .

(Refer Slide Time: 11:22)

And so the condition is, sufficient condition is that which we had seen that the point B should be **this point B should be** there on the arc on the part of the extremal passing through A and A star c. So, that this point B should be their prior to this point A star c, and if it is after that A star c, then we see that around A star c various or around that in the neighborhood of B, there are various extremals intersect each other.

And so, the condition that it is a central field is violated that means, the Jacobi condition is not satisfied there. So, we have to see that the Jacobi condition is fulfilled in order to retain the nature of central field.

(Refer Slide Time: 12:07)

Mathematically, it can be seen that, since $y(x, c)$ satisfies E.E.;

$$F_y(x, y(x, c), y'(x, c)) - \frac{d}{dx} F_{y'}(x, y(x, c), y'(x, c)) = 0. \quad (17.4)$$

Differentiating (17.4) w.r.t. c , we get

$$F_{yy} \frac{dy}{dc} + F_{yy'} \frac{d^2y}{dx^2 dc} - \frac{d}{dx} \left[F_{y'y} \frac{dy}{dc} + F_{y'y'} \frac{d^2y}{dx^2 dc} \right] = 0 \quad (17.4)$$

Let $\frac{dy}{dc}(x, c) = u$ ($F_{y'y} = \frac{d^2y}{dx^2 dc} = \frac{d}{dx} \left(\frac{dy}{dc} \right)$)

$$F_{yy} u + F_{yy'} u_x - \frac{d}{dx} [F_{y'y} u + F_{y'y'} u_x] = 0$$

Since in the above equation no derivative w.r.t. c .

So, that is what is now mathematically derived like this, we differentiate **the we differentiate** Euler's equation partially with respect to c .

(Refer Slide Time: 12:21)

if appearing explicitly, we denote $u_x = u'$, which gives finally

$$\left(F_{yy} - \frac{d}{dx} F_{y'y'} \right) u - \frac{d}{dx} [F_{y'y'} u'] = 0 \quad (17.5)$$

(17.5) is called Jacobi's equation.

We solve (17.5) for u . clearly $u(x, y) = 0$, if u is not zero in the interval $x_1 < x < x_2$ then the Jacobi condition is satisfied.

And see that we get here, finally, this equation that $F_{yy} - \frac{d}{dx} F_{y'y'} u - \frac{d}{dx} F_{y'y'} u' = 0$. So, this equation 17.5 which was derived last time is known as Jacobi's equation.

And so, we solve this and get u and we know that it use equal to 0 at A , and then we see that, whether u vanishes anywhere on the interval x_1 to x_2 . So, if u is not 0 on this open

interval x_1 to x_2 , then we see that Jacobi's condition is fulfilled on that interval. Here we will consider various examples, on this concept.

So, let us take this example.

(Refer Slide Time: 13:12)

Example 18.1

$$I(y) = \int_{x_1}^{x_2} (y'^2 - y^2) dx$$

$$y(x_1) = 0 \quad y(x_2) = 0$$

$$F(x, y, y') = y'^2 - y^2$$

$$F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow -2y - \frac{d}{dx} (2y') = 0$$

$$\Rightarrow y'' + y = 0 \Rightarrow$$

$$y(x) = \alpha \cos x + \beta \sin x$$

$$y(x_1) = 0 \Rightarrow y(x) = C \sin(x - x_1)$$

$y(x_1) = 0$ at $x = x_1 + \pi$.

$x_1 < x_2 < x_1 + \pi$.

$x_2 > x_1 + \pi$ then Jacobi's condition is violated.

(No audio from 13:12 to 13:22)

So, here this functional $I(y)$ is given as integral over x_1 to x_2 y' square minus y square dx , and y at x_1 is 0, and y at x_2 is also 0.

So, we see that here F is x, y, y' is y' square minus y square, and Euler's equation $F_y - \frac{d}{dx} F_{y'} = 0$ implies that $-2y - \frac{d}{dx} (2y') = 0$ or this implies that $y'' + y = 0$. And so, we get $y(x)$ equal to $A \cos x + B \sin x$, thus not use A here. So, we get $y(x)$ equal to $\alpha \cos x + \beta \sin x$. **So, here...**

Now, this condition that y at x_1 is 0 implies that one of the constants will be determined. So, $y(x)$ will be like some constant $C \sin$ of $x - x_1$. So, that is what we see that this solution of this will be one parameter family of curves given by this, and here we see that, and then this $y(x)$ will also vanish at $x_1 + \pi$. So, next $y(x)$ will be 0 at x equal to $x_1 + \pi$.

So, this x_2 , if $0 < x_2$ is for other x_1 lesser than x_2 is $x_1 + \pi$, we see that we have a central field, like this we had seen earlier. Here x_1 is there, and then we have this $x_1 + \pi$ here, and these curves are going like this, and if x_2 is before here, then we see that it forms a central field, and if x_2 is greater than $x_1 + \pi$, then Jacobi's condition **Jacobi's condition** is violated.

(No audio from 17:00 to 17:10)

So, this also can be seen from here, **we form...**

(Refer Slide Time: 17:19)

Jacobi's equation in this case is

$$(F_{yy} - \frac{d}{dx} F_{yy'}) u - \frac{d}{dx} (F_{yy'} u') = 0$$

$$F = y'^2 - y^2,$$

$$(-2) u - \frac{d}{dx} (2 u') = 0$$

$$u'' + u = 0 \Rightarrow$$

$$u(x) = \alpha \cos x + \beta \sin x.$$

$(x_1, y_1) = (x_1, 0)$, $u(x_1) = 0 \Rightarrow u(x) = C \sin(x - x_1)$

$u(x) = 0 \quad x > x_1 \Rightarrow x = x_1 + n\pi$.

The first next zero to $x = x_1$ is $x = x_1 + \pi$.

Hence we must have $x_1 < x_2 < x_1 + \pi$.

So, let us look at the Jacobi's equation in this case is...

(No audio from 17:19 to 17:31)

So, the Jacobi's equation is $F_{yy} - \frac{d}{dx} F_{yy'} u - \frac{d}{dx} (F_{yy'} u') = 0$. So, here F , in this case, we have F is y' prime square minus y square. So, F_{yy} gives you, minus 2 and this $F_{yy'}$ will be 0. And so, minus 2 times u and minus $\frac{d}{dx} F_{yy'}$ it is again 2 here, and u' prime. So, this what we get here? It gives us $u'' + u = 0$. And we get, this implies that $u(x)$ is again like **alpha sin x plus beta alpha cos x and you can writing anyway**, $\alpha \cos x + \beta \sin x$.

And here, we know that u at x_1 must be 0, because the condition is that here, all the extremals pass through that A , which is (x_1, y_1) and (x_1, y_1) is here. So (x_1, y_1) is actually $(x_1, 0)$ here. And so, we get $u(x_1)$ equal to 0 implies that $u(x)$ as before it should be some constant times \sin of x minus x_1 .

So, in the same manner here, **u vanishes at...** So, u then x equal to 0 for x greater than x_1 implies that x must be equal to x_1 plus and pi. And so we have the first 0 will be the first **the first** next zero to x equal to x_1 is x equal to x_1 plus pi. So, **we get...** then hence, we must have x_2 , which is of course, greater than x_1 ; it should be less than x_1 plus pi. So, our interval should be such that it should not contain x_1 plus pi, this interval x_1 to x_2 should not contain the point x_1 plus pi, if it contains, if x_2 is larger than this, then obviously, Jacobi's condition is violated.

Now, the next example...

(No audio from 20:50 to 21:02)

(Refer Slide Time: 20:52)

Example 18.2

$$I(y) = \int_{x_1}^{x_2} [y'^2 + y^2 + x^2] dx$$

$$y(x_1) = 0, \quad y(x_2) = 0.$$

$(F_{yy} - \frac{d}{dx} F_{yy'}) u - \frac{d}{dx} (F_{y'y'} u') = 0$ for
 $F = y'^2 + y^2 + x^2$, reduces to

$$2u - \frac{d}{dx} (2u') = 0$$

$$\Rightarrow u'' - u = 0$$

$$u(x) = c_1 e^x + c_2 e^{-x}$$

$$u(x_1) = 0 \Rightarrow c_1 e^{x_1} + c_2 e^{-x_1} = 0 \Rightarrow \frac{c_1}{c_2} = -e^{-2x_1}$$

$$u(x) = c_1 e^x + c_2 e^{-x} = 2c_1 e^{x_1} \left(\frac{e^{(x-x_1)}}{2} - e^{-\frac{(x-x_1)}{2}} \right)$$

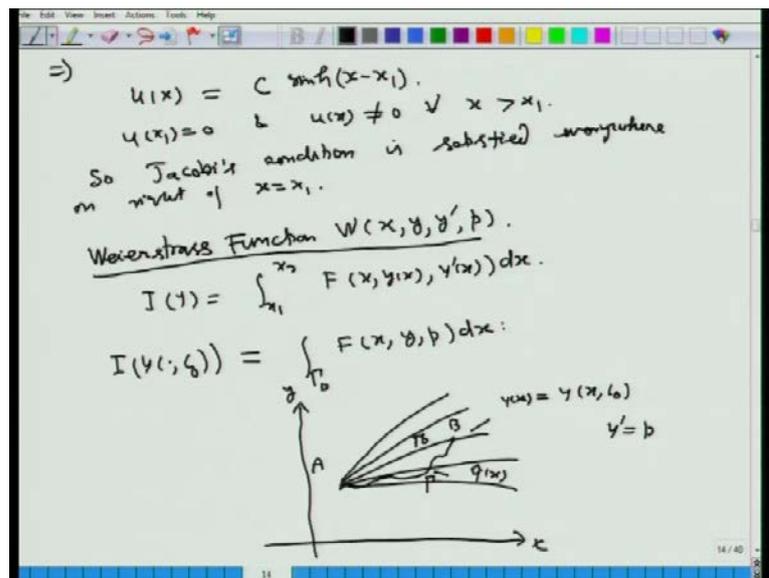

We have this functional $I(y)$ equal to x_1 to x_2 integral y prime square plus y square plus x square dx , here y at x_1 equal to 0, again we take y at x_2 equal to 0. So, the points A and B are on the x axis. And here, so the Jacobi's equation **so** $F_{yy} - \frac{d}{dx} F_{yy'}$ minus $\frac{d}{dx}$ of $F_{y'y'} u'$ prime equal to 0, for F equal to y prime square plus y square plus x square **reduces to...** This gives us **2 y** sorry 2 and this 0. **And**

you get... So, $2u$ here minus d by $d x$, so, I can remove this bracket, $2u$ minus d by $d x$ of this again $2u$ prime equal to 0 .

So, we get here u double prime minus u equal to 0 , which has solution $u(x)$ equal to... we can write in hyperbolic form or you can write it like this that $u(x)$ is $c_1 e$ to the power of x plus $c_2 e$ to power minus x . So, u at x_1 is 0 implies that $c_1 e$ to the power x_1 plus $c_2 e$ to the power minus x_1 equal to 0 is implies that c_1 over c_2 equal to minus e to the power minus $2x_1$.

And so, you get $u(x)$ equal to, which is $c_1 e$ to the power x plus $c_2 e$ to the power minus x becomes $c_1 e$ to the power e to the power x minus x_1 , and with minus sign here, and minus e to the power minus x minus x_1 . And so u multiply by 2 and divide by 2 here, this is plus sign. So, we can take minus of also out and adjust it in this.

(Refer Slide Time: 24:24)

So, we get $u(x)$ equal to some constant C sin hyperbolic x minus x_1 . So, that is the solution of this Jacobi's equation and it vanishes. So, $u(x)$ of course, $u(x_1)$ equal to 0 , and $u(x)$ is not equal to 0 for all x greater than x_1 . So, Jacobi's conditions is verified, is full filled.

(No audio from 25:04 to 25:13)

Is satisfied everywhere, on the right of x equal to x_1 . So, here it forms a central field everywhere.

In the next, what we would like to see that, once the Jacobi's condition is satisfied, you like to get some other conditions, sufficient condition, which will ensure us the **the** sufficient conditions. So, that the functional will have minimum or maximum, we will be able to conclude using that sufficient condition.

So, we construct a function, which is called Weierstrass Function, **Weierstrass Function** which is function of the variables x , y , y' , and p , will explain what is the speed in a moment. So, we have here $I(y)$, which is $\int_{x_1}^{x_2} F(x, y(x), y'(x), p) dx$. Now here, we are taking it on the extremals only that $I(y, c)$ here. So, if we take this extremals, which is what we are testing that is $y(x)$. So, here we have situation already explain like that **that** this is a point $A(x_1, y_1)$, and then we have various extremals like this, and then this $y(x)$ here is actually $y(x, c_0)$.

So, here **this less...** Makes it slightly bigger here.

(No audio from 27:46 to 27:56)

So, this is point A and this point B and this is the curve $y(x)$, which is $y(x, c_0)$. So, fixed value of the parameter c , we have this A, B the **the** extremals passing through these two points, denoted by $y(x)$, and we want to test, whether this extremal actually, extremizes gives you the minimum value of I or the maximum value of I .

So, that is what we would like to see, we would like to get sufficient condition. So that, we can using that sufficient condition, we can ensure that the functional $I(y)$ takes the maximum value or minimum value for this function, which is given by $y(x)$ with this extremals given by $y(x)$, which is $y(x, c_0)$. So, this on this **this** y' , we will denote as p to distinguish between any curve, joining these two points.

Let say, this is the another, this is some curve $\tilde{y}(x)$, it is not an extremals; it is any curve, permissible curve joining these two points A and B. So, like that **we will have...** So, we will denote this by γ_0 , and this general curve γ like this. So, this extremals joining this, these points A and B, so from A to B will denote it as γ_0 . And any other admissible curve joining these two points A and B, it need not be an extremal; we will denote it by γ . So, we will have this $I(y, x_0)$ on γ_0 , which is $\int_{x_1}^{x_2} F(x, y, p) dx$.

(Refer Slide Time: 30:08)

$$I_0(\tilde{y}) = \int_{\Gamma} F(x, y, y') dx.$$
 If we fix $y(x) = y(x, c_0)$, then $I(y)$ is a function of (x_2, y_2) .

$$I_0(y)(x_2, y_2) = \int_{x_1}^{x_2} F(x, y(x, c_0), p(x, c_0)) dx.$$

$$\delta I(y) = dI_0$$

$$dI_0(x_2, y_2) = (F - pF_p) \Big|_{x=x_2} dx_2 + F_p \Big|_{x=x_2} dy_2.$$
 This follows from

$$\delta I(y) = (F - y'F_{y'}) \Big|_{x=x_2} \delta x_2 + F_{y'} \Big|_{x=x_2} \delta y_2.$$
 derived earlier.

And on any other curve, this $I(y)$ tilde, which is then on gamma F of x, y, y' prime $d x$, now, recall that when we considered this also on y , if we fix this $y(x)$, which is $y(x, c_0)$, then **then** this functional $I(y)$ is function now of this point (x_2, y_2) , because now y is fixed and only the point (x_2, y_2) will changing. So, this is a function like this. So, this I let us say, this is y , and then it is like this (x_2, y_2) which is here you have x_1 , which is (x_1, y_1) will fixed and only (x_2, y_2) will changing. So, that is F of $x, y(x), c_0$, and that is your p on y' prime, we are denoting this has $p(x)$, which is something as $p(x, c_0) d x$.

And we have seen that on this the variation delta, since here is a function now. So, this delta $I(y)$ will be denoted as $d I$. So, here to distinguish it from the other functional, we will write it as I_0 . So, this $d I_0$ and $d I_0$ we know that, it will be F minus y' prime $F y'$ prime rather y' prime is p here, $F p$ and delta. So, delta x_2 will be written as $d x_2$.

So, this is the point. **So x 1**, So this is the function of (x_2, y_2) that is F minus $p F p$ of $d x_2$ plus $F p d y_2$. This we had derived earlier, this follows from **this follows from** our from the earlier one, which we have got the delta $I(y)$ was F minus y' prime $F y'$ prime delta x_2 plus F , this was evaluated at x_2 , and then $F y'$ prime delta y_2 , derived earlier.

(No audio from 33:58 to 34:04)

Here, this since only the point B is moving and therefore, this variation, this functional becomes now function, which we denote by I_0 . And so, we have this variation becomes then as usual when it is a function, we denote it by the differential. And so we get differential dI_0 at (x_2, y_2) F minus this of course, is evaluated at this x equal to x_2 , this also at x equal to x_2 .

(Refer Slide Time: 34:51)

For general (x, y) on $\gamma(x)$, we have

$$dI_0(x, y) = (F - pF_p) dx + F_p dy.$$

So, $(F - pF_p) dx + F_p dy$ is exact, is total differential of I_0 .
So its integral is path independent.

Hence

$$\int_{\Gamma} [(F - pF_p) dx + F_p dy]$$

$$= \int_{\Gamma_0} [(F - pF_p) dx + F_p dy]$$

$$= \int_{\Gamma_0} [(F - pF_p) + pF_p] dx$$

$$= \int_{\Gamma_0} F(x, y, p) dx$$

Now here, for general (x, y) so for general (x, y) on $y(x)$, we have this differential dI_0 at (x, y) will be F minus pF_p evaluated x at (x, y) general $(x, y) dx$ plus $F_p dy$. So, we see that this is a total differential the right. So, this F minus $pF_p dx$ plus $F_p dy$ is exact differential, the total differential of dI_0 . And so its integral is path independent.

Thus, hence this integral over any curve γ of this F minus $pF_p dx$ plus $F_p dy$ is same thing as integral over γ_0 , because γ and γ_0 at joining those two points A and B. So, it will be same thing as F minus $pF_p dx$ plus $F_p dy$, but on this we see that on γ_0 , it is F minus $pF_p dx$. So, we take on that curve γ_0 , we see that this we get dx taking out, so plus dy by dx here is p , and so, this is $pF_p dx$, and so this gives us ... So, this cancels here. And so, we get on γ_0 is $F dx$, that is $F(x, y, p) dx$.

(Refer Slide Time: 37:45).

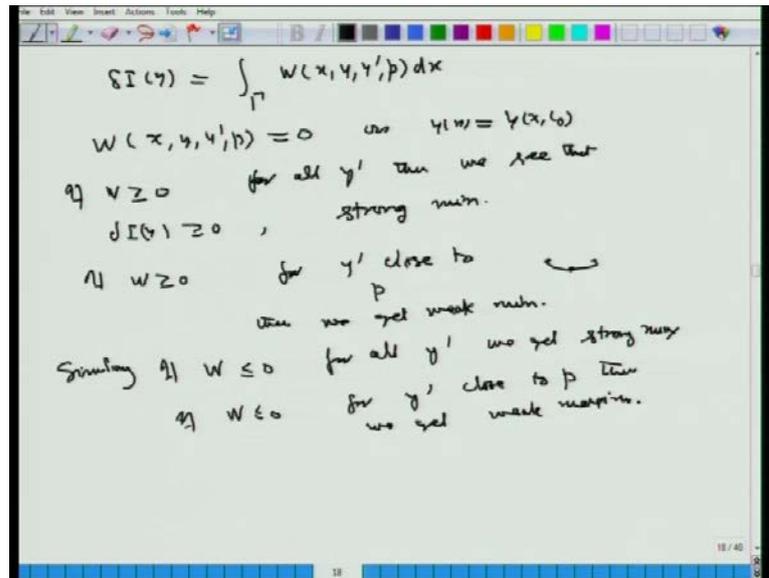

Handwritten mathematical derivation on a whiteboard:

$$\begin{aligned} \text{Hence} \\ \Delta I(y) &= \int_{\Gamma} F(x, y, y') dx - \int_{\Gamma_0} F(x, y, p) dx \\ &= \int_{\Gamma} F(x, y, y') dx - \int_{\Gamma} [(F - pF_p) dx + F_p dy] \\ &= \int_{\Gamma} [F(x, y, y') - F(x, y, p) - (y' - p) F_p(x, y, p)] dx \\ &= \int_{\Gamma} W(x, y, y', p) dx \\ W(x, y, y', p) &= F(x, y, y') - F(x, y, p) - (y' - p) F_p(x, y, p). \end{aligned}$$

So, therefore, hence this increment delta I (y) will be then over this curve gamma F of x, y, y prime d x minus over gamma 0 F x, y here, because it is p d x. And so, this is gamma F x, y, y prime d x, and **this is on the...** This gamma 0 can then be written as an gamma of this F minus p F p d x, and then plus F p d y like this.

And so, this will be then here, it can be written as like this, F of x, y, y prime minus this is F x, y, p and minus y prime minus p F p gave, we get this functional d x. So, here on the gamma this is **F y** x, y that is what we will get here, y prime here. So, this is actually, over this which is W x, y, y prime, p d x, which is Weierstrass Function is given by F x, y, y prime minus F x, y, p minus y prime minus p F p x, y, p.

(Refer Slide Time: 40:36)

Now here, we see that this, so if delta I is, so here we get delta I (y) has integral over this gamma of W x, y, y prime, p d x. Now, W is 0 on, because their W equal to x, y, y prime, p is 0 on y (x), which is y (x, c 0), because here y prime is p. So, we will see that this y prime equal to p. So, this term will be 0 and here also y prime will be p. So, **this term will be** these two terms will be equal and they will be canceled.

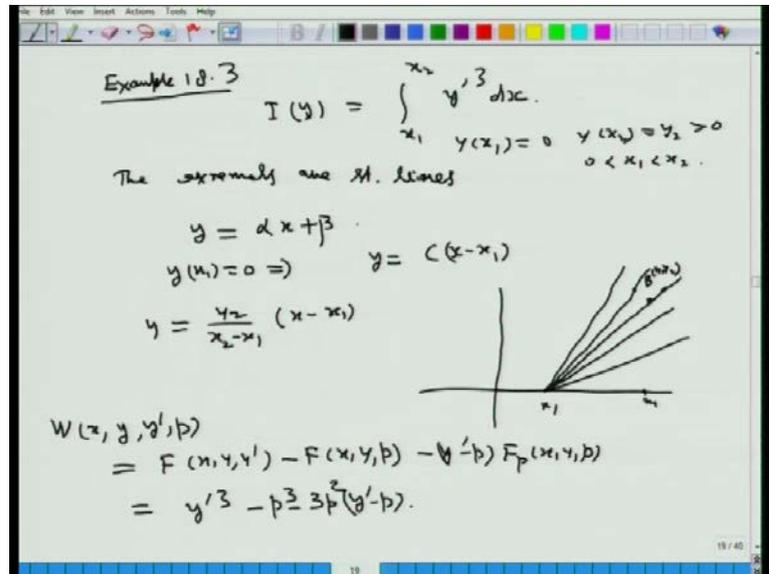

So, this W equal to 0 on this, and now, if W is greater than equal to 0 in the neighborhood of... So, if W is 0, where W is greater than 0 for all y prime, then we see that delta I (y) will be greater than 0. So, in the neighborhood of this y, we will have **strong maximum sorry** strong minimum, like the second order variation, we have that is a **positive** second derivative is greater than equal to 0, we get here minimum.

And so, in this case if delta I (y) is greater than 0, because here than in the neighborhood, you will have it is like this, here you have least value and here in the up it goes, so that the difference here will be positive. So, delta I is greater than equal to 0, we get the minimum and it is independent of y whether y prime, **independent of y prime whether y prime** is close to p or not, because then as we had defined earlier. So, it is in the zero order of proximity. And so, we say that the minimum achieved is strong.

Now, if W greater than equal to 0 for y prime close to p, then we get weak minimum. Similarly, if W is less than equal to 0 for all y prime, we get strong maximum and **if this**

is if W is less than equal to 0 for y prime close to p , then we get weak maximum. So, that is the case here.

(Refer Slide Time: 44:23)

And so let us see the examples now.

(No audio from 44:18 to 44:27)

This would be now... So, now, let us consider this $I(y)$ equal to $\int_{x_1}^{x_2} y^3 dx$, we see that here; it is a function of y prime only. So, the extremals are and the conditions, let say y at x_1 is 0, and y at x_2 is y_2 , we take this to be positive and 0 less than x_1 less than x_2 .

So, the extremals here on straight lines y equal to something like $\alpha x + \beta$, and y at $x_1 = 0$ implies that y equal to $C(x - x_1)$, and here it is y_2 so, you get y equal to $\frac{y_2}{x_2 - x_1}(x - x_1)$. So, this situation here is like this, these are this is the point x_1 and x_2 here. So, this straight lines form the central field here, and let say here x_2, B is here that is (x_2, y_2) and y_2 is taken to be positive here. So, it is here somewhere.

Now, here the Weierstrass Function $W(x, y, y', p)$ is $F(x, y, y') - F(x, y, p) - y'(p) F_p(x, y, p)$. So, this comes out to be, this is $y^3 - p^3 - 3p^2(y - p)$, now y prime is to be replaced by p . So, we get $p^3 - p^3 - 3p^2(y - p)$, so let say $-3p^2(y - p)$.

(Refer Slide Time: 47:36)

$$W = y'^3 - 3y'p^2 + 2p^3 \quad (18.4)$$

$$(y'-p)^2(y'+2p) = (y'^2 + p^2 - 2y'p)(y'+2p)$$

$$= y'^3 - 3y'p^2 + 2p^3 \quad (18.5)$$

From (18.4) & (18.5) we get

$$W = (y'-p)^2(y'+2p)$$

Since $p = \frac{y_2}{x_2 - x_1} > 0$, if y' is close to p then $W \geq 0$. So we have weak min.

So, here we see that, we get W equal to \dots . So this can be seen that, it is y prime cube minus $3 y$ prime p square plus $2 p$ cube, let us put it as 1. And then if we look at this, y prime minus p square into y prime plus $2 p$, this comes out to be y prime square plus p square minus $2 y$ prime p into y prime plus $2 p$. And this is then finally, y prime cube minus $3 y$ prime p square plus $2 p$. So, this is let me put 0, it as 18.4 and this as 18.5.

So, from 18.4 and 18.5, we get that W equal to y prime minus p whole square y prime plus $2 p$. So, here since, p is since p which is y_2 over x_2 minus x_1 is positive. So, if y prime is close to p , then W is greater than equal to 0. And so, we have weak minimum here.

(Refer Slide Time: 49:50)

Example 18.6

$$I(y) = \int_{x_1}^{x_2} (6y'^2 - y'^4 + yy') dx$$

$$y(x_1) = 0 \quad y(x_2) = y_2 > 0, \quad 0 < x_1 < x_2.$$

$$F = 6y'^2 - y'^4 + yy'$$

$$F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow y''(1 - y'^2) = 0$$

$$\Rightarrow y'' = 0 \quad y(x) = \alpha x + \beta.$$

$$y(x_1) = 0 \Rightarrow y(x) = C(x - x_1)$$

$$y(x_2) = y_2 \Rightarrow y(x) = \frac{y_2}{x_2 - x_1} (x - x_1).$$

$$W(x, y, y', p) = F(x, y, y') - F(x, y, p) - (y' - p) F_p(x, y, p)$$

$$= 6y'^2 - y'^4 + yy' - 6p^2 + p^4 - yp.$$

Now the next example, we considered.

(No audio from 49:49 to 49:58)

This $I(y)$ equal to integral x_1 to x_2 $6y'$ prime square minus y' prime to the power 4 plus $y y'$ prime dx . Here, again we have y of x_1 equal to 0 and y at x_2 equal to y_2 , we take positive and $0 < x_1 < x_2$. Here, we have to find first the extremals.

So, here F is $6y'$ prime square minus y' prime 4 plus $y y'$ prime. And so, F_y minus d by dx of $F_{y'}$ prime equal to 0 implies that y'' double prime into $1 - y'$ prime square equal to 0. So, this is not 0, this implies that y'' double prime equal to 0. So, $y(x)$ equal to $\alpha x + \beta$, family of straight lines. So, y at x_1 equal to 0 implies that now we get $y(x)$ equal to $C(x - x_1)$ and passing through this.

So, y at x_2 equal to y_2 implies that $y(x)$ equal to y_2 over $x_2 - x_1$ into $x - x_1$, which is already depicted in the previous example. And here we see that now, this Weierstrass Function here is $y(x) y$ $W(x, y, y', p)$, which is $F(x, y, y')$ minus $F(x, y, p)$ minus $(y' - p) F_p(x, y, p)$, which gives us... Now, in this case $6y'$ prime square minus y' prime 4 plus $y y'$ prime minus $6p^2$ plus p^4 minus yp .

Now, we will see that we will actually get a quadratic equation in that and seeing the roots of that equation, we will be able to conclude in which region, we have a strong

minimum, strong maximum, weak maximum or weak minimum that we will be discussing in the next class. Thank you very much for your attention please.
