Module # 01

Lecture # 36

Welcome viewers once again to the NPTEL lecture series on integral equations. In today's lecture, we are going to discuss about the Fredholm theory to obtain resolvent kernel. Such that, we can find the solution of inhomogeneous Fredholm integral equation of the second kind.

(Refer Slide Time: 00:45)

Fredholm theory of obtain resolvent kernel
for Fredholm integral equation

$$y(x) = f(x) + \lambda \int_a^b K(x,s) y(s) ds$$

The solⁿ of this eqⁿ with the help of Fredholm
resolvent kernel $R(x,s;\lambda)$ is

$$y(x) = f(x) + \lambda \int_a^b R(x,s;\lambda) f(s) ds$$

where $R(x,s;\lambda) = \frac{D(x,s;\lambda)}{\Delta(\lambda)}$, $\Delta(\lambda) \neq 0$

So, we are going to discuss that Fredholm theory to obtain resolvent kernel for Fredholm integral equation, which is given by $y(x) = f(x) + \lambda \int_a^b K(x,s) y(s) ds$.

Now, you can recall that, we have this already discussed other possible methods to solve this kind of integral equation. And also, we have obtained resolvent kernel to find out solution of this non homogeneous Fredholm integral equation of the second kind. But

here, we are going to discuss the method introduced by Fredholm, which is comes out to be ratio of two infinite series, that actually constitute the resolvent kernel. And as per the Fredholm theory the solution of this equation is given by solution of this equation with the help of Fredholm resolvent kernel. (No Audio From: 02:38 to 02:47) $R(x, s; \lambda)$ is $y(x)$ is equal to $f(x)$ plus λ integral a to b $R(x, s; \lambda) f(s) ds$.

(Refer Slide Time: 03:36)

Handwritten notes on a whiteboard:

- $R(x, s; \lambda) \rightarrow$ Fredholm resolvent kernel
- $D(x, s; \lambda) \rightarrow$ Fredholm minor
- $\Delta(\lambda) \rightarrow$ Fredholm determinant
- $$D(x, s; \lambda) = K(x, s) + \sum_{n=1}^{\infty} \frac{(-1)^n \lambda^n}{n!} B_n(x, s)$$
- where,
- $$B_n(x, s) = C_n K(x, s) - n \int_a^b K(x, \xi) B_{n-1}(\xi, s) d\xi$$
- $$B_0(x, s) = K(x, s)$$
- $$n = 1, 2, 3, \dots$$

Where this resolvent kernel $R(x, s; \lambda)$ is a ratio of $\Delta(x, s; \lambda)$ and $\Delta(\lambda)$, where we assume that this $\Delta(\lambda)$ is not equal to 0. And this three quantities $R(x, s; \lambda)$, $D(x, s; \lambda)$ and $\Delta(\lambda)$ this is known as Fredholm resolvent kernel. This $D(x, s; \lambda)$ this is known as Fredholm minor and $\Delta(\lambda)$ this is called Fredholm determinant. (No Audio From: 04:16 to 04:28) And now, we have to find out or define this Fredholm minor and Fredholm determinant. Such that, we can evaluate Fredholm resolvent kernel and which in turn gives us the solution for the Fredholm integral equation. This Fredholm minor $D(x, s; \lambda)$, this is defined by $K(x, s)$ plus $\sum_{n=1}^{\infty} \frac{(-1)^n \lambda^n}{n!} B_n(x, s)$.

Where each $B_n(x, s)$ can be evaluated using this formula $B_n(x, s)$ that is equal to $C_n K(x, s) - n \int_a^b K(x, \xi) B_{n-1}(\xi, s) d\xi$. This formula is valid for n equal to 1, 2, 3 and so on. And in particular $B_0(x, s)$ is defined by $K(x, s)$. So, using this definition $B_0(x, s)$ equal to $K(x, s)$ of course, the formula for Fredholm minor can be written as $B_0(x, s)$ plus $\sum_{n=1}^{\infty} \frac{(-1)^n \lambda^n}{n!} B_n(x, s)$ and so on.

(Refer Slide Time: 06:33)

$$C_n = \int_a^b B_{n-1}(x, x) dx, \quad n = 1, 2, 3, \dots$$

$$C_0 = 1$$

$$\Delta(\lambda) = 1 + \sum_{n=1}^{\infty} \frac{(-1)^n \lambda^n}{n!} C_n$$
Ex. 1
$$K(x, s) = 1 + x + s, \quad -1 \leq x, s \leq 1$$

$$C_0 = 1, \quad B_0(x, s) = K(x, s) = 1 + x + s$$

$$C_1 = \int_{-1}^1 B_0(x, x) dx = \int_{-1}^1 (2x + 1) dx = 2$$

So, we can use this definition. Now, in order to evaluate this $B_n(x, s)$, we need the expression or the values of C_n . These quantities C_n are defined by C_n equal to integral a to b $B_{n-1}(x, x) dx$, where n ranging from 1 2 3 and so on. And in particular C_0 is defined as exactly equal to 1. So, with these definitions for C_0 and C_n . Now, we can define $\Delta(\lambda)$ this is equal to 1 plus sigma n running's from 1 to infinity minus 1 whole to the power n λ^n to the power n by factorial n times C_n . So, this is the definition for $\Delta(\lambda)$, we have already defined $D(x, s, \lambda)$. So, if we able to evaluate each $B_n(x, s)$ and this C_n , then we can find the resolvent kernel, Fredholm resolvent kernel $R(x, s)$.

Now, in some forthcoming examples, you can see that most of the time, we will find that this C_n and B_n are 0 for values of n starting from say two and onwards. So, in most of the cases, you can find first few values C_j 's those are non zero and accordingly first few expressions for B_n those are non zero and rest of the quantities are exactly equal to 0. And this happens most of the times, if we use the kernel's those are separable kernel that is called degenerate kernel. Then most of the cases you can find after some C_j 's first few non zero C_j 's, rest of the C_j 's will be equal to 0. And accordingly we can find those B_n 's are also equal to 0.

And therefore, instead of this infinite series for $\Delta(\lambda)$ and $D(x, s, \lambda)$, most of the time, we will be having a polynomial containing a finite number of terms, because rest of

the terms are identically equal to 0. So, first we consider one example, where we are just defining the kernel which is of course, separable kernel and for that, we construct the Fredholm resolvent kernel using this formula.

So, first example that we can consider $K(x, s)$ this is given by $1 + x + s$, where $-1 \leq x, s \leq 1$. So, you can recall as per definition $C_0 = 1$, $B_0(x, s)$ this is equal to $K(x, s)$. So, this is equal to $1 + x + s$. Next with this B_0 , we can calculate C_1 , you have to keep in mind, that formula for B_n involve C_n and B_{n-1} and formula for C_n involve B_{n-1} , we already have C_0 and B_0 as per definition B_0 is $k(x, s)$.

So, using this expression for $B_0(x, s)$. Now, we can calculate C_1 . So, C_1 this is equal to $-1 \int_{-1}^1 B_0(x, x) dx$. So, this is equal to $\int_{-1}^1 (1 + 2x + 1) dx$. And after evaluating this integral, you can calculate this C_1 is equal to 2, because the integral $\int_{-1}^1 2x dx$ this is equal to 0 and rest of the term will results in 2.

(Refer Slide Time: 10:47)

The image shows a whiteboard with handwritten mathematical derivations. The equations are as follows:

$$B_1(x, s) = C_1 K(x, s) - \int_{-1}^1 K(x, \xi) B_0(\xi, s) d\xi$$

$$= 2(1+x+s) - \int_{-1}^1 (1+x+\xi)(1+\xi+s) d\xi$$

$$= \dots$$

$$= -2\left(xs + \frac{1}{3}\right)$$

$$C_2 = \int_{-1}^1 B_1(x, x) dx = -2 \int_{-1}^1 \left(x^2 + \frac{1}{3}\right) dx = -\frac{8}{3}$$

$$B_2(x, s) = C_2 K(x, s) - 2 \int_{-1}^1 K(x, \xi) B_1(\xi, s) d\xi$$

$$= -\frac{8}{3}(1+x+s) + 4 \int_{-1}^1 (1+x+\xi)\left(\xi s + \frac{1}{3}\right) d\xi = 0$$

Now, for $B_1(x, s)$ as per the given formula, this is C_1 multiplied by $K(x, s)$, then minus integral $\int_{-1}^1 K(x, \xi) B_0(\xi, s) d\xi$. And this will be equal to C_1 , we have already obtained this is equal to 2. So, $2(1+x+s)$ minus integral $\int_{-1}^1 (1+x+\xi)(1+\xi+s) d\xi$, because $k(x, \xi)$ is $1+x+\xi$ and $B_0(\xi, s)$ is actually $K(\xi, s)$. So,

C_1 and C_2 are equal to $1 + \psi + s$ and if you evaluate this integral, then it will result in $\int_{-1}^1 (1 + \psi + s) d\psi = \psi + \frac{1}{2}\psi^2$ evaluated from -1 to 1 , which is $1 + \frac{1}{2} - (-1 + \frac{1}{2}) = 1$. So, we have obtained $C_1 = 1$, with this $C_1 = 1$ we can calculate C_2 , C_2 is equal to $\int_{-1}^1 (1 + \psi + s) d\psi = 1$.

So, this will be equal to $\int_{-1}^1 (-2 + 1 + x^2 + \frac{1}{3}) d\psi$ and after evaluating this integral, you can find this will be equal to $-\frac{8}{3}$. So, now, we have obtained C_2 already we have in our hand $B_1(x, s)$. So, now, we can calculate $B_2(x, s)$, $B_2(x, s)$ is equal to $C_2 K(x, s) - 2 \int_{-1}^1 K(x, \psi) B_1(\psi, s) d\psi$. This is the expression; you can recall already we have defined this formula for B_n . So, therefore, substituting this expression, we can find this will be $-\frac{8}{3}$ multiplied with $1 + x + s$.

And when will be substituting for $B_1(\psi, s)$. So, this $-\frac{8}{3}$ will be clubbed with this $-\frac{8}{3}$. So, we will be having $\int_{-1}^1 (-\frac{8}{3} + 1 + x + \psi) d\psi$ and from here, we will have $\int_{-1}^1 (\psi + \frac{1}{3}) d\psi$. And if you evaluate this integral, then you can find this integral is exactly equal to 0. Now, once you have $B_2(x, s)$ equal to 0.

(Refer Slide Time: 14:08)

The image shows a digital whiteboard with the following handwritten mathematical work:

$$C_3 = \int_{-1}^1 B_2(x, x) dx = 0$$

$$B_3(x, s) = C_3 K(x, s) - 3 \int_{-1}^1 K(x, \psi) B_2(\psi, s) d\psi$$

$$= 0$$

$$C_4 = C_5 = \dots = 0$$

$$B_4(x, s) = B_5(x, s) = \dots = 0$$

$$D(x, s; \lambda) = K(x, s) - \lambda B_1(x, s)$$

$$= 1 + x + s + 2\lambda(xs + \frac{1}{3})$$

$$\Delta(\lambda) = 1 - \lambda C_1 + \frac{\lambda^2}{2} C_2 = 1 - 2\lambda - \frac{4}{3}\lambda^2$$

$$\Delta(\lambda) \neq 0$$

So, therefore, C_3 is equal to $\int_{-1}^1 B_2(x, x) dx$ this should be equal to 0. And once C_3 is equal to 0, then immediately $B_3(x, s)$ according to the formula this is $C_3 K(x, s) - 3 \int_{-1}^1 K(x, \psi) B_2(\psi, s) d\psi$. Now, this C_3

equal to 0 and $B_2(\psi, s)$ equal to 0. So, you will be having B_3 equal to 0 and therefore, you can easily understand that all C_4, C_5 and so on, this constant should be identically equal to 0. Accordingly $B_4(x, \psi), B_5(x, \psi)$ and so on, all of them will be equal to 0. So, as C_3 and onwards are all equal to 0 and B_3 and onwards all these quantities are identically equal to 0.

So, therefore, we can find that $D(x, s, \lambda) = D(x, s, \lambda)$, this will be equal to $K(x, s, \lambda) = B_1(x, s)$, because $B_2(x, s) = 0, B_3(x, s) = 0$. So, none of the term will come here and ultimately you will find this $D(x, s, \lambda)$ is equal to $1 + x + s + 2\lambda$ multiplied with $x + s + \frac{1}{3}$. So, this is actually your $D(x, s, \lambda)$. And $\Delta \lambda$ this will be equal to $1 - 2\lambda - \frac{4}{3}\lambda^2$ plus λ^2 by $2C_2$ and rest of the term C_3, C_4 are all identically equal to 0. So, therefore, will be having, $1 - 2\lambda - \frac{4}{3}\lambda^2$. So, this is the expression for $\Delta \lambda$. So, in case this $\Delta \lambda$ is not equal to 0 assuming this $\Delta \lambda$ not equal to 0.

(Refer Slide Time: 17:00)

The image shows a whiteboard with the following handwritten content:

$$R(x, s; \lambda) = \frac{1 + x + s + 2\lambda(x + \frac{1}{3})}{1 - 2\lambda - \frac{4}{3}\lambda^2}$$

Ex. 2

$$y(x) = x + \lambda \int_0^1 (4xs - x^2) y(s) ds$$

$$K(x, s) = 4xs - x^2$$

$$C_0 = 1, \quad B_0(x, s) = K(x, s) = 4xs - x^2$$

$$C_1 = \int_0^1 B_0(x, x) dx = \int_0^1 3x^2 dx = 1$$

$$B_1(x, s) = C_1 K(x, s) - \int_0^1 K(x, \xi) B_0(\xi, s) d\xi$$

We can obtain the corresponding resolvent kernel, $R(x, s, \lambda)$ this is equal to $1 + x + s + 2\lambda$ multiplied with $x + s + \frac{1}{3}$ whole divided by $1 - 2\lambda - \frac{4}{3}\lambda^2$. So, this is the resolvent kernel, Fredholm resolvent kernel obtained by Fredholm method.

Next, we solve an Fredholm integral equation using the same method. The given problem is $y(x)$ this is equal to x plus λ integral 0 to 1 $4x s$ minus x square $y s$ $d s$. So, this is our problem. So, in this case $K(x, s)$ is equal to $4x s$ minus x square this is our actually kernel. So, our first task is using the Fredholm method, we have to find out the Fredholm resolvent kernel. And for that purpose, we have C_0 equal to 1 $B_0(x, s)$ that is equal to $K(x, s)$ that is equal to $4x s$ minus x square.

Now, we can calculate C_1 , C_1 is equal to integral 0 to 1 $B_0(x, x) d x$. Now, $B_0(x, x)$ this will be equal to $4 x$ square minus x square. So, that means $3 x$ square. So, integral 0 to 1 $3x$ square $d x$ and after evaluating this integral, we can find this is equal to 1 . Next we can calculate $B_1(x, s)$ $B_1(x, s)$, as per definition $C_1 K(x, s)$ minus integral 0 to 1 $K(x, s)$, it will be (x, ψ) multiplied with $B_0(\psi, s) d \psi$.

(Refer Slide Time: 19:40)

The image shows a handwritten derivation on a digital whiteboard. The steps are as follows:

$$B_1(x, s) = 4xs - x^2 - \int_0^1 (4x\zeta - x^2)(4\zeta s - \zeta^2) d\zeta$$

$$= 4xs - x^2 - \int_0^1 (16x\zeta^2 + x^2\zeta^2 - 4x^2\zeta s - 4x\zeta^3) d\zeta$$

$$= 4xs - x^2 - \left[\frac{16}{3}x\zeta^3 + \frac{x^2}{3}\zeta^3 - 4x^2\zeta s - x\zeta^4 \right]_0^1$$

$$= 4xs - x^2 - \left(\frac{16}{3}x + \frac{x^2}{3} - 4x^2s - x \right)$$

$$= 2x^2s - \frac{4}{3}x^2 + x - \frac{4}{3}xs$$

$$C_2 = \int_0^1 B_1(x, x) dx = \int_0^1 \left(2x^3 - \frac{4}{3}x^2 + x - \frac{4}{3}x^2 \right) dx$$

$$= \left[\frac{1}{2}x^4 - \frac{4}{9}x^3 + \frac{1}{2}x^2 - \frac{4}{9}x^3 \right]_0^1 = \frac{1}{9}$$

So, substituting this expression, we can find this $B_1(x, s)$, this will be equal to $4x s$ minus x square because C_1 equal to 1 . So, $C_1 K(x, s)$ is nothing, but $K(x, s)$ minus integral 0 to 1 $4x \psi$ minus x square this multiplied with $4 \psi s$ minus ψ square $d \psi$. This will be equal to $4x s$ minus x square minus integral 0 to 1 $16x s \psi$ plus x square ψ square minus $4x$ square ψs minus $4x \psi$ cube $d \psi$. And evaluating these integral you can find $4x s$ minus x square minus from first one, you can find 16 by $3x s$ plus one-third x square minus. It will be plus $2 x$ square s and then plus x , this will be actually minus, because integral of ψ square probably 0 to 1 is one-third. So, minus 16 by $3 x s$, then ψ square

d psi again one-third. So, minus one-third x square and from here half into 4x square s so, minus if this minus combine will give you plus 2 square s.

And finally, 4x by 4 so, this will be plus x. And after rearranging the terms under simplification, you will be having 2x square s minus 4 by 3 x square plus x minus 4 by 3 x s. So, this is our B 1 (x, s) that, we have calculated and as we know the B value of B x expression for B (x, s). So, we can calculate C 2, C 2 equal to integral 0 to 1 B 1 (x, x) d x. So, this is equal to integral 0 to 1 2 x cube minus 4 by 3 x square plus x minus 4 by 3 x square d x. And after evaluating this integral, this will be half minus 4 by 9 plus half minus 4 by 9 and this will be equal to 1 by 9.

(Refer Slide Time: 22:51)

The image shows a whiteboard with the following handwritten mathematical work:

$$B_2(x, s) = c_2 K(x, s) - 2 \int_0^1 (4xs - x^2) \left(2\frac{s^2}{3} - \frac{4}{3}s^2 + s - \frac{4}{3}xs \right) ds$$

$$= \dots = 0$$

$$c_3 = \int_0^1 B_2(x, x) dx = 0$$

$$B_3(x, s) = 0$$

$$\Delta(\lambda) = 1 - c_1 \lambda + c_2 \frac{\lambda^2}{2} = 1 - \lambda + \frac{\lambda^2}{18}$$

$$D(x, s; \lambda) = 4xs - x^2 - \lambda \left[2x^2s - \frac{4}{3}x^2 + x - \frac{4}{3}xs \right]$$

$$y(x) = x + \frac{\lambda}{1 - \lambda + \frac{\lambda^2}{18}} \int_0^1 D(x, s; \lambda) ds$$

So, this is the value for C 2, with this value for C 2. If we calculate B 2 (x, s) this will be equal to C 2 K (x, s) minus 2 integral 0 to 1 (4 x, psi minus x square). This multiplied with we have to write the expression for B 1 (psi, s). Now, B 1 (psi, s) is 2 psi square s minus 4 by 3 psi square plus psi minus 4 by 3 psi s d psi. And if you evaluate this integral and after simplification it will comes out to be exactly equal to 0.

And once you have B 2 (x, s) this is equal to 0. So, immediately C 3 equal to integral 0 to 1 B 2 (x, x) d x this is equal to 0. And using the formula for B 3 (x, s), you can calculate this is equal to 0. So, C 3 equal to 0 and B 2 (x, s) equal to 0 will give you B 3 (x, s) equal to 0 and therefore, C 4 should be equal to 0. According to the formula C 4 equal to integral 0 to 1 B 3 (x, x) d x and therefore, B 4 (x, s) equal to 0. And hence we have all

the constants C_3, C_4, C_5 and so on; those are identically equal to 0. And the functions $B_2(x, s), B_3(x, s)$ all these functions are also equal to 0; that means, B_4, B_5 all of them are identically equal to 0.

And therefore, delta lambda that is Fredholm determinant is given by $1 - C_1 \lambda + C_2 \lambda^2$ by 2 that is equal to $1 - \lambda + \lambda^2$ divided by 18. And $D(x, s, \lambda)$ this is equal to $4xs - x^2 - \lambda$ into $D_1(x, s)$ that is $2s^2 - s - 4$ by $3x^2 + x - 4$ by $3xs$. This is the expression for $D_1(x, s)$. And therefore, solution to the given problem is $y(x)$ equal to $x + \lambda$ divided by $1 - \lambda + \lambda^2$ by 18, then integral 0 to 1 $D(x, s, \lambda) ds$ because $f(x)$ equal to x . So, $f(s)$ is equal to s .

(Refer Slide Time: 26:16)

$$\text{Ex 3} \quad y(x) = f(x) + \lambda \int_0^1 x e^{\lambda s} y(s) ds$$

$$B_0(x, s) = k(x, s) = x e^{\lambda s}$$

$$C_0 = 1$$

$$C_1 = \int_0^1 x e^{\lambda x} dx = e^{\lambda} (x-1) \Big|_0^1 = 1$$

$$B_1(x, s) = C_1 k(x, s) - \int_0^1 x e^{\lambda x} \int_0^1 \zeta e^{\lambda \zeta} d\zeta$$

$$= x e^{\lambda s} - x e^{\lambda} \int_0^1 \zeta e^{\lambda \zeta} d\zeta$$

$$= x e^{\lambda s} - x e^{\lambda} \cdot 1 = 0$$

So, this is the solution to the given integral equation. Next we consider one more example, this example is taken from Allan Jerry's book on integral equation, where first of all will find out the solution of the given Fredholm integral equation by this method. And then, we will discuss another formula by which you can evaluate the quantities $B_1(x, s), B_2(x, s)$ and so on. And constants C_1, C_2 and so on in terms of repeated integrals. And where integrands are actually determinants of order, $n + 1$ and of order n in respective way.

So, first of all we consider the problem here, the problem is $y(x)$ is equal to $f(x) + \lambda$ integral 0 to 1 $x e^{\lambda s} y(s) ds$, this is the given problem. Clearly $B_0(x, s)$ is

equal to kernel of the given problem $k(x, s)$. So, this is equal to $x e$ to the power s . So, this our kernel and C_0 by definition this is equal to 1. So, now, we can calculate C_1 this is equal to $\int_0^1 x e$ to the $x dx$ evaluating you can find e to the power x into x minus 1 limit 0 to 1 and this will results in this is equal to 1.

Now, if we calculate $B_1(x, s)$ this is equal to $C_1 K(x, s)$ minus $\int_0^1 x e$ to the power s multiplied with ψ e to the power $s dx$. So, this will be equal to since C_1 equal to 1. So, $x e$ to the power s minus, we can take $x e$ to the power s outside the integral $x e$ to the power s then $\int_0^1 \psi e$ to the power $s dx$. Here we have already evaluated $\int_0^1 x e$ to the power $x dx$ equal to 1. So, therefore, this will be equal to $x e$ to the s minus $x e$ to the power s into 1. So, that means, that this is identically equal to 0. So, $B_1(x, s)$ is equal to 0 and once $B_1(x, s)$ is equal to 0.

(Refer Slide Time: 29:00)

The image shows a digital whiteboard with the following handwritten mathematical expressions:

$$C_2 = 0 \Rightarrow B_2(x, s) = 0$$

$$C_n = 0, \quad n = 2, 3, \dots$$

$$B_n(x, s) = 0, \quad n = 1, 2, 3, \dots$$

$$D(x, s; \lambda) = k(x, s) = x e^s$$

$$\Delta(\lambda) = 1 - \lambda C_1 = 1 - \lambda$$

$$R(x, s; \lambda) = \frac{x e^s}{1 - \lambda}$$

$$y(x) = f(x) + \frac{\lambda}{1 - \lambda} \int_0^1 x e^s f(s) ds$$

So, therefore, C_2 this is equal to 0 and C_2 equal to 0 this implies $B_2(x, s)$ this is also equal to 0. And therefore, we can write C_n this is equal to 0 or n equal to 2 3 and so on. And $B_n(x, s)$ this is equal to 0 for n equal to 1 2 3 and so on. So, therefore, $D(x, s; \lambda)$ this is only $K(x, s)$. So, that is equal to $x e$ to the power s . And $\Delta(\lambda)$ this is equal to $1 - \lambda C_1$ since, we have evaluated C_1 equal to 1. So, this will be equal to $1 - \lambda$. And therefore, the resolvent kernel obtained using Fredholm method, that is $R(x, s; \lambda)$ this is equal to $x e$ to the power s divided by $1 - \lambda$ this is the resolvent kernel.

And therefore, solution to the given problem is given by $y(x)$ equal to $f(x)$ plus λ , whole divided by $1 - \lambda \int_0^1 x e^{-s x} ds$, this is the solution to the given integral equation. Now, we define the alternative way by which, we can calculate this $B_n(x, s)$ and C_n . Of course, we have to keep in mind that $B_0(x, s)$ is nothing, but $K(x, s)$ and C_0 is also equal to 1.

(Refer Slide Time: 31:12)

Alternative way of expressing $B_n(x, s)$ and C_n

$$B_n(x, s) = \int_a^b \int_a^b \dots \int_a^b \begin{vmatrix} K(x, s_1) & K(x, s_2) & \dots & K(x, s_n) \\ K(s_1, s) & K(s_1, s) & \dots & K(s_1, s_n) \\ \dots & \dots & \dots & \dots \\ K(s_n, s) & K(s_n, s_1) & \dots & K(s_n, s_n) \end{vmatrix} ds_1 ds_2 \dots ds_n$$

$$C_n = \int_a^b \int_a^b \dots \int_a^b \begin{vmatrix} K(s_1, s_1) & K(s_1, s_2) & \dots & K(s_1, s_n) \\ K(s_2, s_1) & K(s_2, s_2) & \dots & K(s_2, s_n) \\ \dots & \dots & \dots & \dots \\ K(s_n, s_1) & K(s_n, s_2) & \dots & K(s_n, s_n) \end{vmatrix} ds_1 ds_2 \dots ds_n$$

So, the alternative way to expressing $B_n(x, s)$ and C_n .

(No Audio From: 31:12 to 31:29)

$B_n(x, s)$ and C_n and here this alternative way one sense it is important. That in earlier method, you have observed that calculation of $B_n(x, s)$ depends up on the x value of C_n . And the expression for $B_{n-1}(x, s)$ and evaluation C_n was related to the expression for $B_{n-1}(x, s)$.

Now, in this alternative approach, we do not need the expressions for B_{n-1} in order to calculate C_n and the value of C_n and the expression for B_{n-1} in order to evaluate $B_n(x, s)$. So, first of all we define, this $B_n(x, s)$ is equal to $\int_a^b \int_a^b \dots \int_a^b$. Then determinant $K(x, s)$ $K(x, s_1)$ up to $K(x, s_n)$, this is the first row. Second row $K(s_1, s)$ $K(s_1, s_1)$ proceeding in this way $K(s_1, s_n)$ finally, last row will be $K(s_n, s)$ $K(s_n, s_1)$. Last term $K(s_n, s_n)$, this determinant $ds_1 ds_2$ up to ds_n , this is the expression for $B_n(x, s)$.

And C_n this is defined by integral a to b , integral a to b , integral a to b , this determinant $K(s_1, s_1) K(s_1, s_2)$ up to $K(s_1, s_n)$ this is the first row. Second row $K(s_2, s_1) K(s_2, s_2)$ dot dot $K(s_2, s_n)$ proceeding in this way. Last row will be $K(s_n, s_1) K(s_n, s_2)$ last term is $K(s_n, s_n)$, then $d s_1 d s_2$ up to $d s_n$. So, in both these cases although, we have to evaluate these n th ordered integrals, but from previous examples what we have discussed, you can able to understand. Using the property of determinant we will be able to prove that B_n will be equal to 0 for values of n say 3 4 and onwards or for example, say 2 3 and onwards.

Now, with this alternative definition for the expression of $B_n(x, s)$ and C_n , we can solve the last problem, that we have just solved that is the $y(x)$ equal to $f(x)$ plus integral 0 to 1 $x e$ to the power $s f(s) d s$ multiplied by λ . So, this problem, we are going to solve using these definitions for $B_n(x, s)$ and C .

(Refer Slide Time: 35:51)

The image shows a whiteboard with the following handwritten mathematical expressions:

$$C_0 = 1, \quad B_0(x, s) = x e^s$$

$$C_1 = \int_0^1 \kappa(s_1, s_1) ds_1 = \int_0^1 s_1 e^{s_1} ds_1 = 1$$

$$B_1(x, s) = \int_0^1 \begin{vmatrix} \kappa(x, s) & \kappa(x, s_1) \\ \kappa(s_1, s) & \kappa(s_1, s_1) \end{vmatrix} ds_1$$

$$= \int_0^1 \begin{vmatrix} x e^s & x e^{s_1} \\ s_1 e^s & s_1 e^{s_1} \end{vmatrix} ds_1$$

$$= e^s \int_0^1 \begin{vmatrix} x & x \\ s_1 & s_1 \end{vmatrix} ds_1 = 0$$

So, C_0 equal to 1, $B_0(x, s)$ this is equal to $x e$ to the power s . Now, you can see that C_1 this will involve only one integral, that is integral 0 to 1 $d s_1$ and here determinant consist of only one term that is, we are having 1 plus 1 determinant that is a scalar quantity $K(s_1, s_1) d s_1$. So, this will be integral 0 to 1 $s_1 e$ to the power $s_1 d s_1$ this is equal to 1. Then $B_1(x, s)$ this is equal to integral 0 to 1 second order determinant $K(x, s) K(x, s_1)$, then $K(s_1, s)$ and then $K(s_1, s_1) d s_1$. And if we substitute the expressions so, this is will be 0 to 1 determinant $x e$ to the power $s x e$ to the power s_1 ,

then $s_1 e$ to the power s_1 and s_1 this will be $s_1 e$ to the power s and this is $s_1 e$ to the power $s_1 d s_1$.

So, from the first row, first column sorry, first column we can take e to the power s common from the second column we can take out e to the power s_1 column common. So, e to the power s integral 0 to 1 e to the power s_1 , then determinants $x s_1 x s_1 d s_1$ this determinant is 0.

(Refer Slide Time: 38:07)

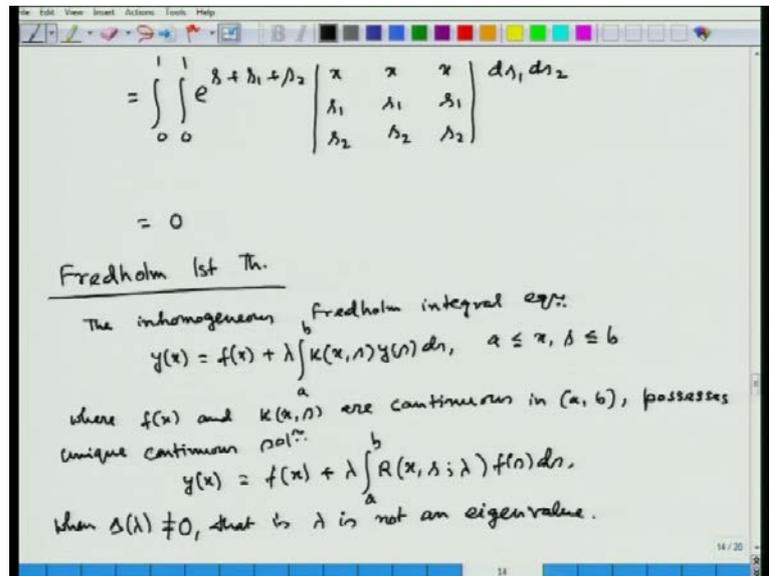

The image shows a whiteboard with handwritten mathematical derivations. The first part shows the calculation of C_2 as a double integral from 0 to 1 of a 2x2 determinant of kernels $K(s_1, s_1)$ and $K(s_2, s_2)$ with respect to ds_1, ds_2 . This is simplified to a double integral of a determinant with entries $s_1 e^{s_1}$ and $s_2 e^{s_2}$. The next step shows that this determinant is zero because the two columns are identical, both being $(s_1, s_2)^T e^{s_1 + s_2}$. The final part shows the expression for $B_2(x, s)$ as a double integral of a 3x3 determinant with entries πe^{s_1} , $s_1 e^{s_1}$, $s_2 e^{s_1}$ in the first column and πe^{s_2} , $s_1 e^{s_2}$, $s_2 e^{s_2}$ in the second and third columns, with respect to ds_1, ds_2 .

So, clearly $B_1(x, s)$ is equal to 0. Next, if we calculate C_2 , this will be equal to double integral 0 to 1 0 to 1 determinant $K(s_1, s_1)$, then $K(s_1, s_2)$. Second row $K(s_2, s_1)$ and then $K(s_2, s_2) d s_1 d s_2$, if we substitute the expressions for kernels, it will be $s_1 e$ to the power s_1 , then $s_1 e$ to the power s_2 , then $s_2 e$ to the power s_1 and $s_2 e$ to the power $s_2 d s_1 d s_2$. So, if we take out the exponential from the determinant that means taking e to the power of s_1 from the first column. And e to power of s_2 from the second column, then e to power of $s_1 + s_2$ multiplied with first column $s_1 s_2$ second column of the determinant is again $s_1 s_2 d s_1 d s_2$ so, this is equal to 0.

So, although, here we do not have any link between b_2 and c_2 in order to evaluate them using this alternative method. So, this c_2 is equal to 0 now, in order to understand the rest of the expressions for b_3 and onwards will be equal to 0. We can just have a look at expression for B to x , if we look at expressions for $B_2(x, s)$, this will be double integral 0 to 1, 0 to 1 a third order determinant. I am not writing the that is $K(x, s)$ I am directly

substituting these expressions. First row will consist of x e to the power s then x e to the power $s - 1$ and then x e to the power $s - 2$. Then second row will be $s - 1$ e to the power s , $s - 1$ e to the power $s - 1$ e to the power $s - 2$.

(Refer Slide Time: 40:50)

And third row is $s - 2$ e to the power s then $s - 2$ e to the power $s - 1$ and then $s - 2$ e to the power $s - 2$ with respect to $d s_1 d s_2$. And you can write this is equal to integral 0 to 1 integral 0 to 1 e to the power s plus $s - 1$ plus $s - 2$ multiplied with determinant first row x $s - 1$ $s - 2$, second row column x $s - 1$ $s - 2$, third column x $s - 1$ $s - 2$ all these columns are identical. So, determinant is exactly equal to 0 and therefore, $B_2(x, s)$ is also equal to 0. So, proceeding in this way and if you are able to understand this argument, all other determinants involve with $B_3(x, s)$ $B_4(x, s)$ will produce this kind of determinant each of which will be identically equal to 0.

And therefore, all other $B_2(x, s)$, $B_3(x, s)$ are identically equal to 0 and also, this kind of determinant will be involved with c_j 's also. And therefore, all the c_j 's except C_0 and C_1 are identically equal to 0. So, you will be having all these quantities are identically equal to 0. Now, before concluding this lecture I define three theorems of Fredholm and before defining those theorems. I just want to recall that in the last lecture, we have considered one example, where we have discussed about Eigen values and Eigen functions associated with the homogeneous Fredholm integral equation. You can recall

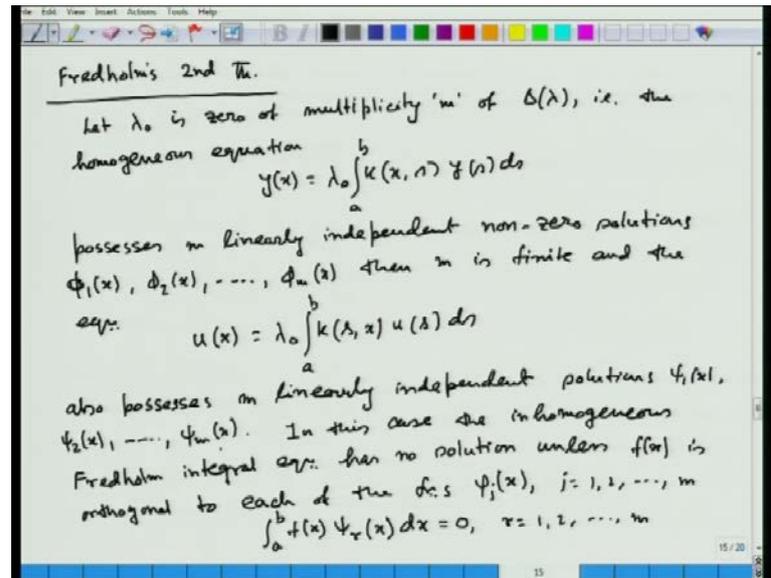

that in case of homogeneous Fredholm integral equation, we have Eigen values and Eigen functions.

And with an elastic example, we have discussed in detail that sometimes those equations may not have any nontrivial solutions. And if they have some nontrivial solution, then sometimes they admit infinite number of solutions. So, whenever this λ satisfies the condition $\Delta \lambda = 0$; that means, if we choose a particular value of λ , which is a 0 of the function $\Delta \lambda$.

Or in other words those are the Eigen values of the associative homogeneous problem, then what will be the nature of solution and in which case we will be having infinite number of solutions, those can be summarized by three theorem of Fredholm. So, first of all we consider Fredholm first theorem. It states that, the inhomogeneous Fredholm integral equation $y(x) = f(x) + \lambda \int_a^b K(x, s) y(s) ds$, where $a \leq x \leq b$ this is the range of x and $K(x, s)$ are continuous in finite interval (a, b) possesses unique solution, (No Audio From 44:43 to 44:49) unique continuous solution (No Audio From 44:53 to 44:59) given by $y(x) = f(x) + \lambda \int_a^b R(x, s) f(s) ds$, when $\Delta \lambda \neq 0$, that is λ is not an Eigen value.

In case $\Delta \lambda \neq 0$; that means λ is not an Eigen value, then this Fredholm integral equation possesses unique continuous solution. That is given by this one, this $R(x, s)$ is $R(x, s, \lambda)$. Here I have written in intended to mean the Fredholm resolvent kernel, but of course, by using other method you can also calculate this resolvent kernel which will be a solution of this Fredholm integral equation. Then second theorem states that in this case we are assuming that the particular λ involve with the equation say $\lambda = 0$ which is an Eigen value.

(Refer Slide Time: 46:19)

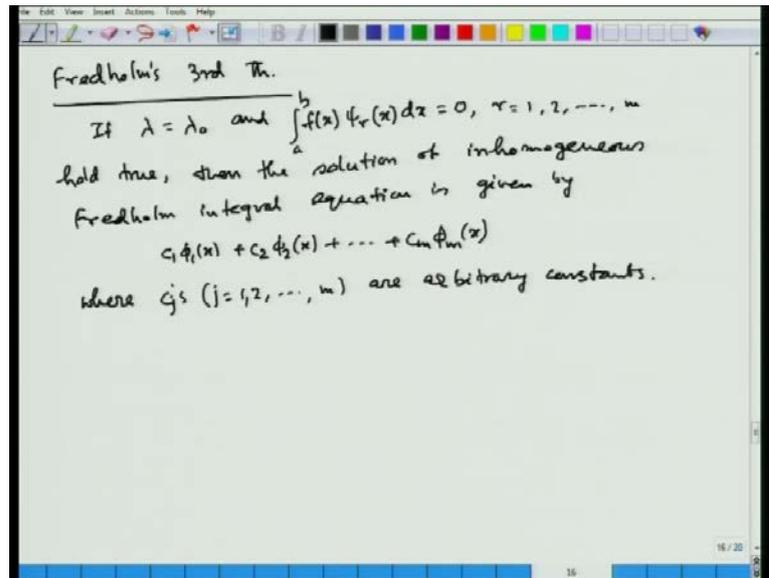

So, this is Fredholm's second theorem. It states that let λ_0 is 0 of multiplicity m of $\Delta(\lambda)$. That is the homogeneous equation $y(x) = \lambda_0 \int_a^b K(x,s) y(s) ds$ possesses m linearly independent non-zero solutions which are denoted by $\phi_1(x), \phi_2(x), \dots, \phi_m(x)$. Then m is finite and the equation $u(x) = \lambda_0 \int_a^b K(x,s) u(s) ds$ also possesses m linearly independent solutions which are denoted by $\psi_1(x), \psi_2(x), \dots, \psi_m(x)$.

In this case the inhomogeneous Fredholm integral equation that we have written earlier has no solution unless $f(x)$ is orthogonal to each of the functions $\psi_j(x)$ for j running's from 1 2 up to m . That is $\int_a^b f(x) \psi_r(x) dx = 0$ for $r = 1, 2, \dots, m$. So, will have non-trivial solution whenever this condition that is $\int_a^b f(x) \psi_r(x) dx = 0$; that means, this $f(x)$ is orthogonal to each of the eigen function $\psi_1(x), \psi_2(x), \dots, \psi_m(x)$ and these $\psi_1(x), \psi_2(x), \dots, \psi_m(x)$. These are the eigen functions of the problem defined by $u(x) = \lambda_0 \int_a^b K(x,s) u(s) ds$.

And last Fredholm theorem that is the Fredholm third theorem. That gives us whenever this condition is satisfied; that means $f(x)$ satisfies the condition that is $\int_a^b f(x) \psi_r(x) dx = 0$. That means, it is orthogonal to each of the eigen functions $\psi_1(x), \psi_2(x), \dots, \psi_m(x)$. Then the nontrivial solution of the equation is given by as a linear combination of this eigen functions. This is the Fredholm's third theorem.

(Refer Slide Time: 51:20)

If lamda equal to lamda 0 and integral a to b f x psi r x d x this is equal to 0 where r equal to 1, 2, 3 up to m hold true. Then the solution of inhomogeneous Fredholm integral equation is given by C 1 phi 1 x plus C 2 phi 2 x plus dot dot plus C n phi n x where c j's, j running from 1, 2 m are arbitrary constants. So, these are actually three Fredholm's theorem associated with the Fredholm integral equation the second kind and in case this lamda is not an Eigen value of the associated homogeneous problem. And f x and K (x, s) that is kernel, those are continuous over the interval a, b then we have unique solution.

And in case lamda equal to lamda 0 which is an enfold eigen value or a 0 of delta lamda of multiplicity m. Then we will be having m eigen functions and if f x satisfies this orthogonality condition that is integral a to b f x psi r x d x equal to 0 for r running's from 1 to m. Then we have infinite number of solutions for the inhomogeneous Fredholm integral equation because this C 1 C 2 up to C n these are all arbitrary constants. And the linear combination of this eigen functions that is C 1 phi 1 x plus C 2 phi 2 x plus up to dot dot that is C n phi m x. This will be the solution of this last term will be C m phi m x where c j is ranging from 1 to m. This is the infinite number of solutions for the inhomogeneous Fredholm integral equation.

Today I stop at this point. In next lecture, we will be considering hill ward smith theory for these Fredholm integral equations. Thank you for your attention.
