Finite length string vibrations (continued)

Welcome back in the last video we have seen vibration of a finite string when both the ends of the strings are fixed that means the displacement is 0 at both the ends, we have seen how find the solution by separation of variables method. So in this video we will just see we will try to do one more problem something similar problem where the finite string is one end is attached and one end is fixed one end is kind of free and other end is fixed. So we will see this how what is the vibration of the string for all the times we will just find solutions by the separation of variables taking.

(Refer Slide Time: 1:10)

The slide contains the following handwritten content:

Problem: $\nu u_{tt} - c^2 u_{xx} = 0, \quad 0 < x < L, \quad t > 0$

I.C.: $\left. \begin{aligned} u(x, 0) &= f(x) \\ u_t(x, 0) &= g(x) \end{aligned} \right\} 0 < x < L$

B.C.: $\left. \begin{aligned} u_x(0, t) &= 0 \\ u(L, t) &= 0 \end{aligned} \right\} t > 0$

Solu.: Let $u(x, t) = X(x) T(t) (\neq 0)$

$X(x) T''(t) = c^2 X''(x) T(t)$

On the right side, there is a diagram of a string of length L along the x -axis. The left end is at $x=0$ and the right end is at $x=L$. The boundary conditions are indicated as $u_x(0) = 0$ and $u(L) = 0$. The initial conditions are indicated as $u(x, 0) = f(x)$ and $u_t(x, 0) = g(x)$. A vertical dashed line at $x=L$ is labeled "wave eqn".

$$\text{Soln: Let } u(x,t) = X(x)T(t) (\neq 0)$$

$$X(x)T''(t) = c^2 X''(x)T(t)$$

$$\Rightarrow \frac{T''(t)}{c^2 T(t)} = \frac{X''(x)}{X(x)} (= \lambda)$$

$$X''(x) - \lambda X(x) = 0, \quad 0 < x < L \quad ; \quad T''(t) - \lambda c^2 T(t) = 0, \quad t > 0.$$

$$\text{B.C.1: } u(0,t) = 0 \Rightarrow X'(0)T(t) = 0 \Rightarrow X'(0) = 0$$

$$\text{B.C.2: } u(L,t) = 0 \Rightarrow X(L)T(t) = 0 \Rightarrow X(L) = 0$$

So this video we will start with this initial boundary value problem so that is consider problem we have this consider this finite string so let us today let us chose from 0 to L, so a string of length L which is one end is at 0, other end is at L you consider this one end you fix it as u at L equal to 0 so you fix it this end you make it free so that is u x at 0 equal to 0. So at this this is the boundary you have solution and you can see that this is your time t and this is your x axis so you have wave equations satisfied here wave equation is satisfied here so within this strip so within this strip infinite strip you have wave equations satisfied initial conditions are u at x at t equal to 0 is given f x and u t at velocity of this string at t equal to 0 that is also given so these are the this is the complete well defined problem.

So we will just write it $u_{tt} - c^2 u_{xx} = 0$ for x is between 0 to L t is positive, so this is your differential equation and your initial data initial data is initial conditions are u at x equal to 0 x t equal to 0 is f x and u t at x, 0 is g x for x is between 0 to L so this is your data for 0 to L that means you have a at initial time you have displacement and velocity of the string is known.

Boundary conditions one end is fixed, other end is free so you have u x partial derivative with respect to x at x equal to 0 for all times you make it 0 and u is fixed at displacement is fixed displacement is 0 at the other end that is at x equal to L for all times equal to 0. So this is true for every t positive, okay for all times this is true. So this is the problem so we need to find a solution so u of x, t for every x and t.

So solution as usual just look for solution because it is a finite domain so you see that if you look at the domain of x t domain so x domain is bounded 0 to L, t domain is actually positive

so you have a this actually t is only positive so this is your domain this is your domain is not this $(0, \infty)$ than 0, okay so this is within this this kind of this is the kind of domain so you have this is your domain within this wave equation is true and we have the initial data is here and we have boundary data.

So look for solution let $u(x, t)$ be solution in a separable form, so that is $X(x), T(t)$ which is nonzero we look for solution in this form then you substitute into the equation so wave equation so you have $T''(t)X(x) = c^2 X''(x)T(t)$ that is what if you substitute to this equation. So divide because this is nonzero you divide with $X(x)$, $T(t)$ that is $X(x)$ into $T(t)$ if we divide both sides you see that $T''(t)$ divided by bring this c^2 here you have $T(t)$ so $X(x)$ cancels I brought this c^2 here so you have $X''(x)$ divided by $X(x)$ divided $X(x)$, $T(t)$, $T(t)$ $T(t)$ of t goes so this is what you have.

So variables are separated so should be that means and both are same functions of x left hand side functions of t . So that means it has to be constant so call this the parameter λ . And now from this x is ordinary differential equation so if you consider this you have $X''(x) - \lambda X(x) = 0$, x is the domain 0 to L , okay and what happens to the other one.

So for t you have other ODE that is $T''(t) - \lambda c^2 T(t) = 0$ this is for t positive. So these are the two ODE's you have, clearly you see that this is in the self adjoint form so we can easily see that so this is equation in the self adjoint form so we will see so you apply $u(x, t)$ so boundary conditions $u(x, 0) = 0$ boundary condition 1 implies this so this implies boundary condition 1 is this.

So this implies if you apply what you get is $X'(x)$ so that is what is your $X'(x)$ of 0 into $T(t)$ that is what is $u_x(x, 0)$, t if you differentiate this is what you get. So this is equal to 0 , $T(t)$ cannot be 0 as a function of t implies $X'(0) = 0$. Now you apply the boundary condition 2 will give me $u(L, t) = 0$ this will give me $X(L)T(t)$ has to be 0 that means $T(t)$ cannot be 0 so you have $X(L) = 0$.

(Refer Slide Time: 7:30)

$$X''(x) - \lambda X(x) = 0, \quad 0 < x < L$$

$$X'(0) = 0, \quad X(L) = 0.$$

$$LX(x) = (1 \cdot X')' + 0 \cdot X = \lambda \cdot 1 \cdot X$$

$$p(x) = 1, \quad q(x) = 0, \quad w(x) = 1, \quad \langle \phi, \psi \rangle := \int_0^L \phi(x) \overline{\psi(x)} dx.$$

$$\Rightarrow \lambda \text{ is real} \Rightarrow \lambda = \mu^2 \text{ or } \lambda = 0 \text{ or } \lambda = -\mu^2 \text{ with } \mu > 0.$$

$$\lambda = \mu^2: \quad X'' - \mu^2 X = 0$$

$$X(x) = c_1 e^{\mu x} + c_2 e^{-\mu x}.$$

So extracted Sturm-Liouville problem that is for X of x where is λX of x equal to 0 is between 0 to L and you have X' at 0 equal to 0 which is equal to X at L , so $X(L)$ equal to 0 so you can write separately so these are the boundary conditions. So we can see that this is clearly in the self adjoint form like P is 1 X' of whole dash that is the first term so minus plus q 0 into X q 0 equal to λ into w of x that is 1 into X . So this is in the self adjoint form so P x is 1, q x is 0, w x equal to 1, so this is what you need.

So w x equal to 1 implies the dot product you can define the dot product call this Φ_n or Φ_i and Ψ_i dot product we can define it as integral domain is 0 to L $\Phi_i \cdot \Psi_i$ dx , okay. So these are the steps so now consider so implies now because this is in the self adjoint form (8:54) form this is L y equal to this is my L X of X , okay so this is my L X so there is L is in the self adjoint form.

So implies all lambdas are real implies a λ is a real that means λ is μ^2 or λ is equal to 0 or λ is equal to minus μ^2 with μ positives, okay. So look at all these three cases consider λ equal to μ^2 first you what is the equation, equation becomes $X'' - \mu^2 X$ equal to 0 and so the general solution is $c_1 \mu x e^{\mu x} + c_2 e^{-\mu x}$.

(Refer Slide Time: 9:51)

$$X'(0) = 0 \Rightarrow \mu (c_1 - c_2) = 0$$

$$\Rightarrow c_1 = c_2 \checkmark$$

$$X(x) = 2c_1 \cosh \mu x \checkmark$$

$$X(L) = 0 \Rightarrow 2c_1 \cosh \mu L = 0$$

$$c_1 = 0 = c_2 \checkmark$$

$$X(x) = 0, \forall x \Rightarrow \lambda = \mu^2 \text{ is not an eigenvalue.}$$

$$\lambda = 0: X'' = 0$$

$$\Rightarrow X(x) = c_1 x + c_2 \checkmark$$

$$X'(0) = 0 \Rightarrow c_1 = 0$$

$$X(x) = c_2$$

$$X(L) = 0 \Rightarrow c_2 = 0 \checkmark$$

$$\Rightarrow X(x) = 0, \forall x \Rightarrow \lambda = 0 \text{ is not an eigenvalue.}$$

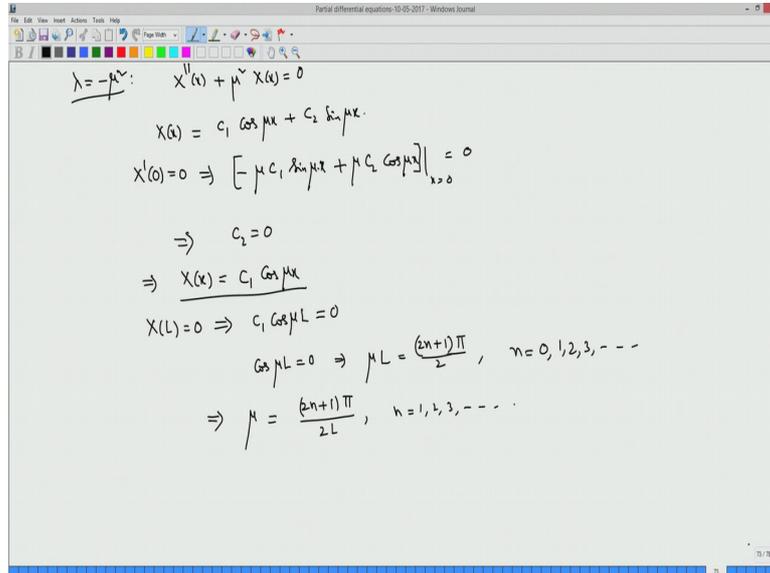

Now you apply boundary conditions $X'(0) = 0$ will give me $\mu c_1 - c_2$ equal to 0 so that is what is the first equation. So it will give me μ cannot be 0, μ is positive so c_1 has to be equal to 0. Apply $X(L) = 0$ then what happens once you get c_1 equal to 0 what happens to the general solution general solution is simply $c_1 = c_2$. So you have $c_1 = c_2$ by we can make it $2c_1$ so divide by 2 so that will be $\cosh \mu x$ that is what it becomes. So $X(L)$ now if you apply this other boundary condition for this general solution of you have $X(L)$ so $2c_1 \cosh \mu L$ equal to 0.

So $\cosh \mu L$ can never be 0 this is always positive because exponential some of the exponential functions never be 0. So that means this cannot be 0, $2c_1$ cannot be 0 that means c_1 has to be 0 if c_1 is 0 from $c_1 = c_2$ which is equal to c_2 so both are 0. So my general solution becomes 0 completely, okay for every x . So implies $\lambda = \mu^2$ is not an eigenvalue.

So look at the case now the $\lambda = 0$, so you have $X'' = 0$, $\lambda = 0$ so equal to 0. So this now you get $X(x) = c_1 x + c_2$ so that is the general solution, you apply the boundary condition $X'(0) = 0$ will give me $c_1 = 0$. So you have the general solution becomes after applying the boundary condition 1 you get c_2 .

Now if you apply the other boundary condition X at L (2) L equal to 0 will give me c_2 has to be 0 . So implies X of x is completely 0 , for every x , implies 0 is not λ equal to 0 is not an eigenvalue.

(Refer Slide Time: 12:21)

$$\lambda = -\mu^2: \quad X''(x) + \mu^2 X(x) = 0$$

$$X(x) = c_1 \cos \mu x + c_2 \sin \mu x$$

$$X'(0) = 0 \Rightarrow \left[-\mu c_1 \sin \mu x + \mu c_2 \cos \mu x \right]_{x=0} = 0$$

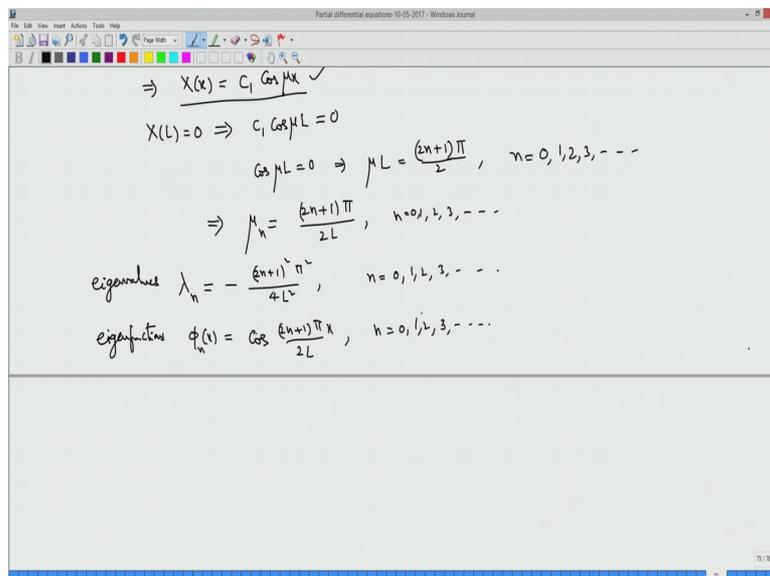

$$\Rightarrow c_2 = 0$$

$$\Rightarrow X(x) = c_1 \cos \mu x$$

$$X(L) = 0 \Rightarrow c_1 \cos \mu L = 0$$

$$\cos \mu L = 0 \Rightarrow \mu L = \frac{(2n+1)\pi}{2}, \quad n = 0, 1, 2, 3, \dots$$

$$\Rightarrow \mu = \frac{(2n+1)\pi}{2L}, \quad n = 1, 2, 3, \dots$$

$$\Rightarrow X(x) = c_1 \cos \mu x$$

$$X(L) = 0 \Rightarrow c_1 \cos \mu L = 0$$

$$\cos \mu L = 0 \Rightarrow \mu L = \frac{(2n+1)\pi}{2}, \quad n = 0, 1, 2, 3, \dots$$

$$\Rightarrow \mu_n = \frac{(2n+1)\pi}{2L}, \quad n = 0, 1, 2, 3, \dots$$

$$\text{eigenvalues } \lambda_n = -\frac{(2n+1)^2 \pi^2}{4L^2}, \quad n = 0, 1, 2, 3, \dots$$

$$\text{eigenfunctions } \phi_n(x) = \cos \frac{(2n+1)\pi x}{2L}, \quad n = 0, 1, 2, 3, \dots$$

So the only option is λ equal to $-\mu^2$ this is what you can actually directly write so always you give Sin, Cosine, Sin solutions always give sometimes 0 , okay. So if you do this you have X'' of x minus $-\mu^2 X$ of x equal to 0 . So this is the ODE now. So the solution is general solution is general solution becomes $c_1 \cos \mu x$ plus $c_2 \sin \mu x$.

Apply the boundary conditions $X'(0) = 0$ on this you get $c_2 = 0$ so what is this one gives me $-\mu c_1 \sin \mu x + \mu c_2 \cos \mu x$ at $x = 0$ so that is 0 , okay $-\mu c_1 \sin \mu x + \mu c_2 \cos \mu x$ at $x = 0$

equal to 0 equal to 0 so this whole thing at x equal to 0. So this means you have this is 0 so that means c_1 is arbitrary so what you get is $c_2 \mu$ is anyway positive $\cos \mu$ into 0 that is 1 so c_2 equal to 0. So what happens now your general solution becomes $c_1 \cos \mu x$.

Now you apply other boundary condition $(X=L)$ X at L equal to 0 will give me $c_1 \cos \mu L$ equal to 0 so c_1 is 0 or $\cos \mu L$ is 0, $\cos \mu L$ can be 0 for certain μ positive values, okay. So so for those μ values c_1 can be arbitrary. So that means so you have a nonzero solution for such μ values by taking c_1 as nonzero. So if you so we want a nonzero solution so that means you make a $\cos \mu L$ equal to 0 implies I know that it has a solutions μL equal to $2n$ plus 1 by 2 π , okay and running from n is from 0, 1, 2, 3 onwards. If you put n equal 0 that is π by 2 $\cos \pi$ by 2 is 0.

So this is how you get so this implies I have all these μ which is $2n$ plus 1 π by $2L$, n is running from 1, 2, 3 and so on. So for these μ values μ is depending on n so we call this μ_n , so you have λ_n these are eigenvalues λ_n 's are minus μ square that is $2n$ plus 1 whole square π square by $4L$ square. So these are your eigenvalues, n is from 0 onwards 0, 1, 2, 3 and so on.

And what are the eigenfunctions eigenfunctions what are the eigenfunctions basically you have a c_1 is arbitrary here in the solution so $\cos \mu$ so that is you call this eigenfunctions Φ_n of x we call them $\cos \mu_n$, so what is μ_n $2n$ plus 1 π by $2L$ x again n is running from 0, 1, 2, 3 and so on. So these are your eigenvalues and eigenfunctions. So corresponding to this n equal to 1, 2, 3 take this as a λ and try to now you solve completely this problem. So now construct we choose those eigenvalues in the place of λ and try to solve this ordinary differential equation for t .

(Refer Slide Time: 16:23)

$$T_n''(t) + \frac{(2n+1)^2 \pi^2}{4L^2} T_n(t) = 0, \quad n=0,1,2,3, \dots$$

$$\Rightarrow T_n(t) = A_n \cos \frac{(2n+1)\pi c}{2L} t + B_n \sin \frac{(2n+1)\pi c}{2L} t, \quad \checkmark$$

$$A_n, B_n \text{ are arbitrary constants.}$$

Assume that

$$u(x,t) = \sum_{n=0}^{\infty} u_n(x,t) = \sum_{n=0}^{\infty} \cos \frac{(2n+1)\pi x}{2L} \left(A_n \cos \frac{(2n+1)\pi c t}{2L} + B_n \sin \frac{(2n+1)\pi c t}{2L} \right) \text{ also a soln}$$

Satisfying B.C.'s.

So you have $T''(t) + \lambda c^2 T(t) = 0$, where $\lambda = \frac{(2n+1)^2 \pi^2}{4L^2}$. So you have this is your λ so because T depending on n for each λ $\lambda = n^2$ so it is depending on so calling it the ODE for each n I have a differential equation like this $T_n''(t) + \lambda c^2 T_n(t) = 0$, okay. So $T_n''(t) + \lambda c^2 T_n(t) = 0$, $\lambda = \frac{(2n+1)^2 \pi^2}{4L^2}$, $\lambda c^2 = \frac{(2n+1)^2 \pi^2 c^2}{4L^2}$, this is what you get when again n is from 0, 1, 2, 3 onwards.

So this will give me clearly $T_n(t)$ as you call this for each n two arbitrary constant I am calling it $A_n \cos \frac{(2n+1)\pi c t}{2L}$. So this is $\cos \frac{(2n+1)\pi c t}{2L}$ so $\lambda = \frac{(2n+1)^2 \pi^2}{4L^2}$ so $\lambda c^2 = \frac{(2n+1)^2 \pi^2 c^2}{4L^2}$ so λc^2 is basically have a square. So you have a square here so missed here so $\frac{\pi c}{2L}$ that is $\frac{\pi c}{2L}$ into t so this is \cos of this number. So root of this number this whole thing I am writing it here so \cos at number into t plus other arbitrary constant B_n with $\sin \frac{(2n+1)\pi c t}{2L}$. So these are your solutions where A_n, B_n are arbitrary constants, okay.

So what happens to your solutions $u_n(x,t)$ for each n you have $u_n(x,t)$ that is x of x that is what is your x of x that is your calling it eigenfunctions. So if you call it x of n so this is $\cos \frac{(2n+1)\pi x}{2L}$, so $\cos \frac{(2n+1)\pi x}{2L}$ by into $\frac{\pi x}{2L}$ into $T_n(x) T_n(t)$ is this one. So if you write this $A_n \cos \frac{(2n+1)\pi x}{2L} + B_n \sin \frac{(2n+1)\pi x}{2L}$. So this is what you have u_n .

So this if you make a sum of all solutions n is now running from 0 to infinity, n is now running from 0 to infinity there is we call it $u(x,t)$ be the solution, okay each term is a solution of wave equation satisfying the boundary conditions so assume that assume that

assume that this sum this infinite sum make sense and assume that it is a solution by super position of all the each of the solutions, okay assume that is a solution is also a solution satisfying boundary conditions.

(Refer Slide Time: 20:13)

$$\text{I.C 1: } u(x, 0) = f(x)$$

$$\sum_{n=0}^{\infty} A_n \cos \frac{(2n+1)\pi x}{2L} = f(x)$$

$$A_n = \frac{\int_0^L f(x) \cos \frac{(2n+1)\pi x}{2L} dx}{\int_0^L \cos^2 \frac{(2n+1)\pi x}{2L} dx}$$

$$A_n = \frac{2}{L} \int_0^L f(x) \cos \frac{(2n+1)\pi x}{2L} dx, \quad n=0,1,2,3,\dots$$

$$\text{Denom} = \int_0^L \frac{1 + \cos \frac{(2n+1)\pi x}{L}}{2} dx$$

$$= \frac{L}{2} + \frac{\sin \frac{(2n+1)\pi x}{L}}{\frac{(2n+1)\pi}{L}} \Big|_0^L$$

$$= \frac{L}{2}$$

Now what is if it is a solution only thing is A n, B n's are not known arbitrary constants still to be determined. So make use of initial data initial condition 1 that is u at x, 0 equal to f x. So if you put u left hand side u at x, 0 is that is Cos so Cos if you put n is from 0 to infinity u at x so Cos as it is 2n plus 1 Pi x by 2L and if we put t equal to 0 so B n will be will not be there. So you have A n Cos so you have that is 1 so that is what it is equal to f x and we put t equal to 0 only A n. So this whole thing is A n, okay.

So how do from this you can get your A n's A n's for each n simply multiply this x n's okay make it dot product so multiply and integrate from 0 to L that is what is your that is where is you are using this dot product from the Sturm-Liouville problem. So because these are all the functions these are all real lambda is real and eigenfunctions are also real so because Cosine all these are real so bar does not make does not matter.

So you have A n's 0 to L right hand side of 0 to L A n you will get A n as integral 0 to L that is right hand side f x x n of x that is Cos 2n plus 1 Pi x by 2L dx this one and the left hand side when you multiply again with Cos same Cos 2n plus 1 Pi x by 2L only A n's will remain with the integral. So that integral if you divide it so we get 0 to L Cos square 2n plus 1 Pi x by 2L so that is what is so this you can evaluate the denominator so the integral in the denominator you can actually evaluate and you can write it.

So if you evaluate this $1 + \cos\left(\frac{2n\pi x}{L}\right)$ so that is $2n\pi x$ by L right divided by 2 , so this is from 0 to L this is what you will get, okay. So if you do this you will see that if you integrate from 0 to L so 0 to L that is what you will get so this is the integrant so $2 \cos^2$ half of this that is what is this divided by 2 , okay this is from 0 to L . So you get $\cos\left(\frac{2n\pi x}{L}\right)$ so that is actually it will become $\cos\left(\frac{2n\pi x}{L}\right)$ so that is 1 by 2 so you have that is what is you have to integrate this this is what is the 0 to L .

So you can write this as this this is your dx that is the integral denominator denominator is this. So you have this is L by 2 plus this will be $\sin\left(\frac{2n\pi x}{L}\right)$ into L by $2n\pi$ plus 1 Pi this if you do it from 0 to L this is a constant comes out L if you substitute that is 0 0 . So you simply have L by 2 . So when you can write this as A_n as $\frac{2}{L} \int_0^L f(x) \cos\left(\frac{2n\pi x}{L}\right) dx$, n is running from $0, 1, 2, 3$ and so on, so this is how you get your a_n 's by applying the initial condition 1.

(Refer Slide Time: 24:31)

The image shows a handwritten derivation on a whiteboard. At the top, the coefficient A_n is defined as $A_n = \frac{2}{L} \int_0^L f(x) \cos\left(\frac{2n\pi x}{L}\right) dx$, with $n = 0, 1, 2, 3, \dots$. To the right, a calculation shows $A_0 = \frac{2}{L} \int_0^L f(x) dx = \frac{2}{L} \cdot \frac{L}{2} = 1$. Below this, the initial condition 2 is given as $u_t(x, 0) = g(x)$. This is equated to the series $\sum_{n=0}^{\infty} \cos\left(\frac{2n\pi x}{L}\right) \cdot B_n \cdot \frac{2n\pi c}{L} = g(x)$. Solving for B_n , it is shown that $B_n = \frac{2}{L} \int_0^L g(x) \cos\left(\frac{2n\pi x}{L}\right) dx$. Finally, the coefficient B_n is given as $B_n = \frac{4}{(2n+1)\pi c} \int_0^L g(x) \cos\left(\frac{(2n+1)\pi x}{L}\right) dx$, with $n = 0, 1, 2, 3, \dots$.

So in this solution the super position solution I know what is my A_n , so if I find B_n by applying the initial condition 2 and through. So I C 2 initial condition 2 is u_t at $x, 0$ is $g(x)$, g is given this is the data given. So you have n is from 0 to infinity. Now you have $A \cos\left(\frac{2n\pi x}{L}\right)$ plus 1 Pi x by $2L$ this is A_n if you now if you differentiate this with respect to t then you will get and put t equal to 0 \cos becomes \sin and you put t equal to 0 that is 0 so this will not be contributing.

So what you will have is here $2n\pi c$ by $2L$ into cosine of that. So if you differentiate this with respect to t $2n\pi c$ by $2L$ \cos at t equal to 0 that is 1 so you have into B_n so

this into B_n is so this is your number so this is your number, this is your function so this is equal to $g(x)$. Now again you can see that from this if you apply the dot product both sides you can see that $2n + 1$ πc by $2L$ into B_n you can get it as again 2 by L integral 0 to L $g(x)$ by the same way like earlier so you have $g(x) \cos 2n + 1 \pi x$ by $2L dx$, okay.

So this gives me $B_n B_n$ as so L , L goes 4 by $2n + 1 \pi c$ into 0 to L $g(x) \cos 2n + 1 \pi x$ by $2L dx$, so again n is from $0, 1, 2, 3$ onwards. So now I know what is my A_n 's and B_n 's in this general solution so this is your general solution. So this is the solution that satisfy all the condition.

(Refer Slide Time: 27:02)

The slide contains the following handwritten text and diagram:

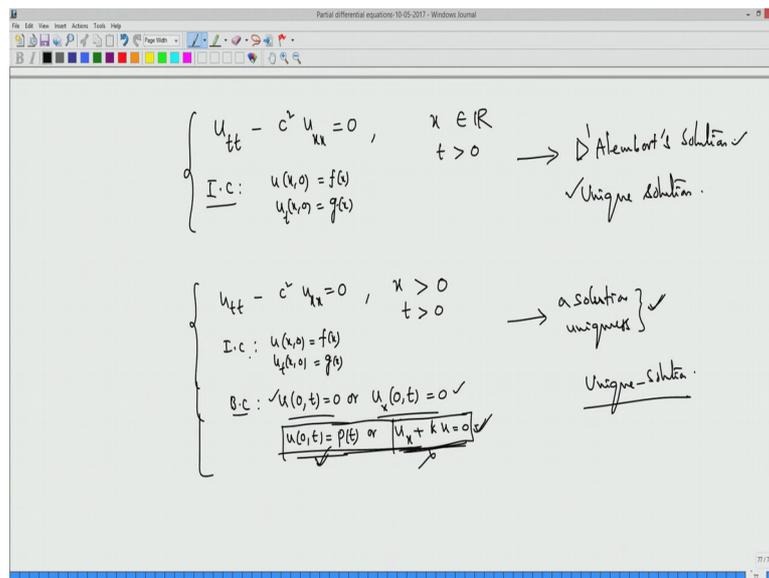

$$\Rightarrow \underline{u(x,t) = \sum_{n=0}^{\infty} u_n(x,t)}$$
 is the required solution.

 Below the equation is a diagram consisting of a horizontal line with a checkmark at the right end. The label $u=0$ is written at both the left and right ends of the line.

So implies u of x, t take a super position of all the solutions of u_n of x, t with this A_n 's and B_n 's is the required solution. So these are the vibrations you can see for all times for a finite length of string string of finite length that is one end is fixed, other end is lefted free. So that is how this is how it vibrates so you have this solution, okay. So you can also do the other problems when the string is both ends are lefted free so you can allow both ends are 0 , u_x is 0 here and u_x is also 0 here.

So you can work out bring extract this Sturm Liouville problem with different boundary conditions so you find the eigenvalues and eigenfunctions, then apply the initial conditions to get the solution in a separable form. So nicely you get vibration of string whatever may be the boundary conditions, okay so leave it as an exercise for you to work out remaining problems, okay.

(Refer Slide Time: 28:13)

So far what we have done so let us recap what we have done so $u_{tt} - c^2 u_{xx}$ this is your wave equation so what you have is x belongs to the full real line t positive you only have the initial data that is u at x equal to 0 equal to $f(x)$ given at t at x equal to 0 is $g(x)$ because there is no boundary this has a solution. So this is the D'Alembert's solution we found we had a solution D'Alembert's solution and you have a solution for this problem and we have also seen that this is the unique solution by the energy argument by considering the energy you have the unique solution uniqueness is also proved, okay so you have a unique solution you have shown that D'Alembert's solution is the unique solution for this problem this initial problem for the wave equation on a full domain you have an infinite string infinite string at both ends when you give the displacement and the velocity initially you know that vibration of the string for all time you know as a D'Alembert's solution that is actually that is D solution is because of uniqueness.

And we also have seen how to reduce some problems in a same problem but when you consider a semi-infinite domain. So x is positive and t is positive and initial conditions are same that is $u(x,0) = f(x)$ $u_t(x,0) = g(x)$ because you now you have the boundary you have a boundary condition so you can give the boundary condition as either fixed it or allow it to be free. So $u(0,t) = 0$ or $u_x(0,t) = 0$.

So in each case we simply extend the domain into extend all the functions involved even or odd functions and then extend the domain as a full real line and make use of this D'Alembert's solution and we find the solution so you have a solution, okay we have a solution. And we also have seen that uniqueness uniqueness is shown, okay uniqueness is

shown by the same energy argument earlier. So you have again unique solution, so in this case, okay.

And if you change this to different things for example u at $0, t$ as some general function P of t still you can actually show the uniqueness solution you can work out by the general way. So without extending even or odd function we can also just by looking at the general solution of the wave equation and then make use of the boundary condition for to find the arbitrary functions one in the negative side.

So by that method you can actually seen the solution and again energy argument you can show works uniqueness is there so you have the unique solution even in this case, only problem is when you have this absorbing boundary condition u_x plus u constant times u so if you attach with some string then you may not have you have not shown the uniqueness unique solution but it is little tricky so it is not straight forward but you have the solution is uniqueness unique solution is there one can prove uniqueness solution by different argument but we are not giving so this you need not worry.

So there also we can work out similar solutions this this we have not given these two solutions but we can work out by the general argument, you have a solution and that is actually unique but I have not shown here and one can show the uniqueness uniqueness argument by the energy argument you can show the uniqueness even in this case for the for the same problem with these boundary condition, okay. So this is what you have seen.

So now let us look at the initial value problem here, so this initial value problem as a non-homogeneous function so if you consider this is a forcing is 0 there is no forcing outside force external force is 0 here. So you have a wave equation there is no external force initially these are the this is what you have. so if you give some forcing outside from the forcing so you can write f of x, t for all times you can give some function let us say some h of x, t if you give as a forcing term, okay.

Partial differential equations-19-05-2017 - Windows Journal

Non-homogeneous wave equation:

$$u_{tt} - c^2 u_{xx} = h(x,t), \quad \begin{matrix} x \in \mathbb{R} \\ t > 0 \end{matrix}$$

Uniqueness is true.
Find a solution.

I.C.: $\begin{cases} u(x,0) = f(x) \\ u_t(x,0) = g(x) \end{cases}$

NPTEL

So let us say non-homogeneous equation so non-homogeneous equation so if we will write this non-homogeneous equation okay. So let me write non-homogeneous wave equation so let us take this full domain so $u_{tt} - c^2 u_{xx} = h(x,t)$ equal to some h of x, t given this is a forcing external force for x belongs to full \mathbb{R} and t positive so you have full infinite string and you have the initial data u at again $x, 0$ is $f(x)$ and u_t at $x, 0$ equal to $g(x)$ so this is your initial data.

So we want to know how do we find the solution here so again by the same energy argument one can show that by the same argument if you assume u_1, u_2 are two solutions for this problem, okay for this problem if you consider two solutions u_1 and u_2 of x, t and u_1 and u_2 be two solutions, you take the difference that you call it w , w is the solution of the wave equation with no forcing because if u_1 satisfies this you take the difference it will be 0.

So h right hand side will be 0, simply satisfies the homogeneous wave equation and the initial data will be 0, 0. So by using the energy same energy argument whatever have given earlier proof that works even here so that you have the uniqueness of the solution uniqueness is guaranteed uniqueness uniqueness is true, only thing you have to find the solution one needs to find a solution so that you have a unique solution even for this non-homogeneous wave equation, okay.

So that is what this is what we will show in the next video, I will just give you we will give you the method to find solution we will try to break this problem into two parts one is you already know that it is a D'Alembert's solution homogeneous part and non-homogeneous

solution that particular thing you can get the solution by simple integration taking it. So we will see this in the next video, thank you very much.
