Numerical Solution of ODE-4
Runge - kutta Methods

(Refer Slide Time: 00:16)

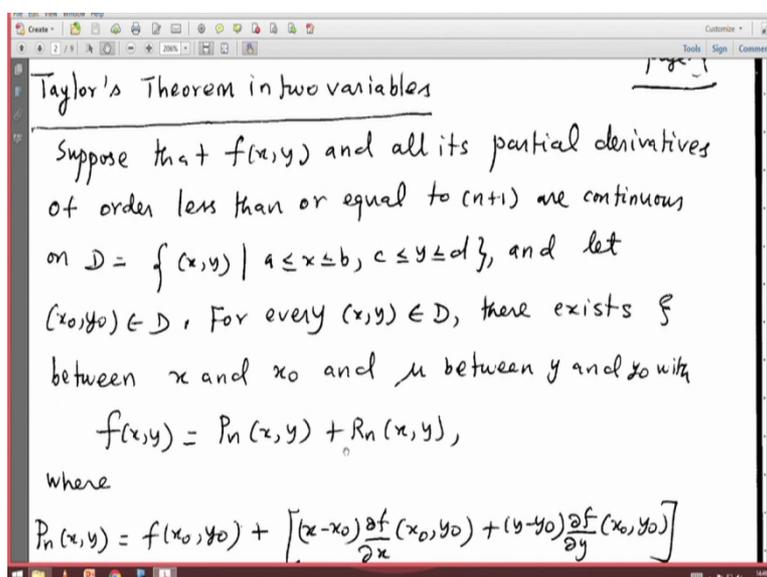

So let us recall what we have stated about Taylor series method? The Taylor series method has the desirable property of high order local truncation error but it also has some disadvantages namely it requires computation and evaluation of the derivatives of $f(x,y)$ and it is a complicated time consuming procedure for most problems then $f(x,y)$ is complicated. And it is too expensive for most practical problems and it is seldom used in practice because of the computational effort which are required to carry out the details.

(Refer Slide Time: 01:06)

So as I said earlier this leads us to look for other single step methods which imitate Taylor Series method without the necessity of computing higher order derivatives, such methods are Runge - kutta Methods. They mimic the Taylor series method let us see how and then derive Runge - kutta Methods of different orders.

(Refer Slide Time: 01:36)

The derivation requires the knowledge of Taylor's theorem in two variables. So let us quickly go through this result. Namely Taylor's theorem for the function of two variable which says that suppose $f(x,y)$ and all its partial derivatives of order less than or equal to n plus 1 are

continuous on a rectangle R which consists of points x, y with x lying between a and b and y between c and d, and if (x_0, y_0) is in R then for every x, y in R there exists a ξ between x and x_0 and μ between y and y_0 with $f(x, y)$ equal to $P_n(x, y)$ plus $R_n(x, y)$.

(Refer Slide Time: 02:28)

where

$$P_n(x, y) = f(x_0, y_0) + \left[(x-x_0) \frac{\partial f}{\partial x}(x_0, y_0) + (y-y_0) \frac{\partial f}{\partial y}(x_0, y_0) \right]$$

$$+ \left[\frac{(x-x_0)^2}{2!} \frac{\partial^2 f}{\partial x^2}(x_0, y_0) + (x-x_0)(y-y_0) \frac{\partial^2 f}{\partial x \partial y}(x_0, y_0) + \frac{(y-y_0)^2}{2!} \frac{\partial^2 f}{\partial y^2}(x_0, y_0) \right]$$

$$+ \dots$$

$$+ \left[\frac{1}{n!} \sum_{j=0}^n \binom{n}{j} (x-x_0)^{n-j} (y-y_0)^j \frac{\partial^n f}{\partial x^{n-j} \partial y^j}(x_0, y_0) \right]$$

and

Where $P_n(x, y)$ is $f(x_0, y_0)$ plus $(x-x_0)$ into partial derivative of f with respect to x evaluated at (x_0, y_0) plus $(y-y_0)$ into partial derivative of f with respect to y at (x_0, y_0) plus the higher order terms plus etc plus the term involving the n th order partial derivative. That constitutes $P_n(x, y)$.

(Refer Slide Time: 03:05)

$$R_{n+1}(x, y) = \frac{1}{(n+1)!} \sum_{j=0}^{n+1} \binom{n+1}{j} (x-x_0)^{n+1-j} (y-y_0)^j \frac{\partial^{n+1} f}{\partial x^{n+1-j} \partial y^j}(\xi, \mu),$$

and

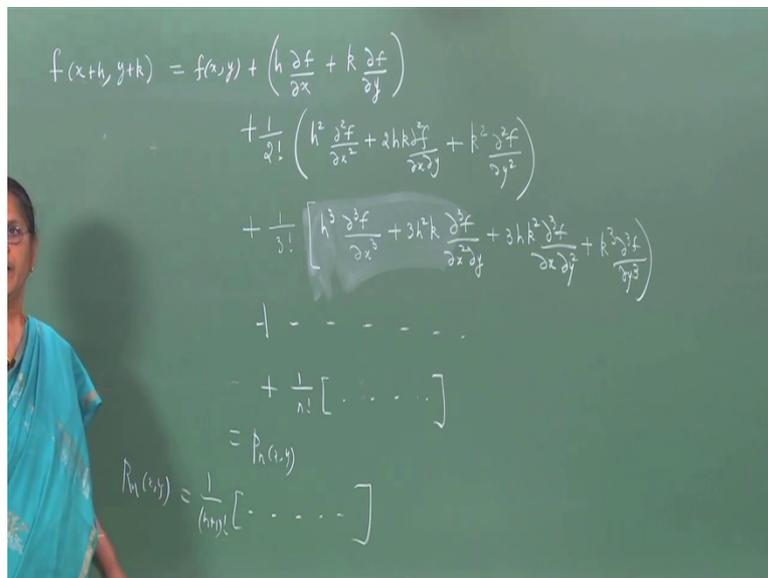

$P_n(x, y) \rightarrow$ is called the n th Taylor polynomial is two variables for the function f about (x_0, y_0)

$R_n(x, y) \rightarrow$ is the remainder term associated with $P_n(x, y)$.

And $R_n(x,y)$ is the rest of the terms which is given by $\frac{1}{(n+1)!} \sum_{j=0}^{n+1} \binom{n+1}{j} (x-x_0)^{n+1-j} (y-y_0)^j$ into $n+1$ th derivative of f with respect to x $n+1-j$ times with respect to y j times evaluated at (x_0, y_0) . This R_n is called the remainder term associated with P_n and $P_n(x,y)$ is the n th Taylor polynomial in two variables for the function f about (x_0, y_0) .

This is not something new to you you have already learned that when you have discussed function of two variables in your calculus course. So let us just recall it in the same notation in which you would have learned.

(Refer Slide Time: 04:15)

So let us look at the board and write down the details. So if I have a function of 2 variables and I give a small increment h to the first argument and an increment k to the second argument. Then using Taylor series it is given by $f(x, y)$ plus the increment in the first argument that is h multiplied by the partial derivative of f with respect to the first variable for which h is the increment plus increment in the second argument which is k into partial derivative of f with respect to the second variable y for which k is the increment.

So this is set of terms which involve first order partial derivatives. Now we go to the next term which is $\frac{1}{2!}$ into h^2 into the second order derivative of f with respect to x plus $2hk$ into the second order derivative of f with respect to x with respect to y which is a next partial derivative plus k^2 into second order derivative with respect to y twice.

Let us write down the third term which is 1×3 factorial h^3 into the third derivative of f with respect to x plus $3 h^2 k$ into third derivative of f with respect to x twice and y once plus $3 h k^2$ into third derivative of f with respect to x once and y twice and then k^3 into the third derivative of f with respect to y twice and so on.

So if I move on upto $1 \times n$ factorial into the terms that is what I call as $p_n(x, y)$ to this I should add $R_n(x, y)$ which will be the first neglected term after this which will involve $1 \times (n + 1)$ factorial into the terms which involve derivatives of f which are partial derivatives of f of order $n + 1$ with respect to x with respect to y suitably. This is what we have written there.

(Refer Slide Time: 07:15)

$$\begin{aligned}
 f(x, y) &= f(x_0 + h, y_0 + k) \\
 &= f(x_0, y_0) + \left[(x-x_0) \frac{\partial f}{\partial x} + (y-y_0) \frac{\partial f}{\partial y} \right] \\
 &\quad + \frac{1}{2!} \left[(x-x_0)^2 \frac{\partial^2 f}{\partial x^2} + 2(x-x_0)(y-y_0) \frac{\partial^2 f}{\partial x \partial y} + (y-y_0)^2 \frac{\partial^2 f}{\partial y^2} \right] \\
 &\quad + \dots \\
 &\quad + \frac{1}{n!} \left[\dots \right] \\
 &\quad + R_n(x, y) \\
 &\quad \hookrightarrow = \frac{1}{(n+1)!} \left[\dots \right]
 \end{aligned}$$

How we want $f(x, y)$ we want to expand about the point x_0, y_0 so I rewrite this as $(x - x_0) + x_0, (y - y_0) + y_0$. So I want to expand about x_0, y_0 , so my increment is $(x - x_0)$ to the first variable and $(y - y_0)$ to the second variable. So it is $f(x_0, y_0)$ plus the increment given to the first variable is $(x - x_0)$ into partial derivative of f with respect to x increment given to the second variable into partial derivative of f with respect to y .

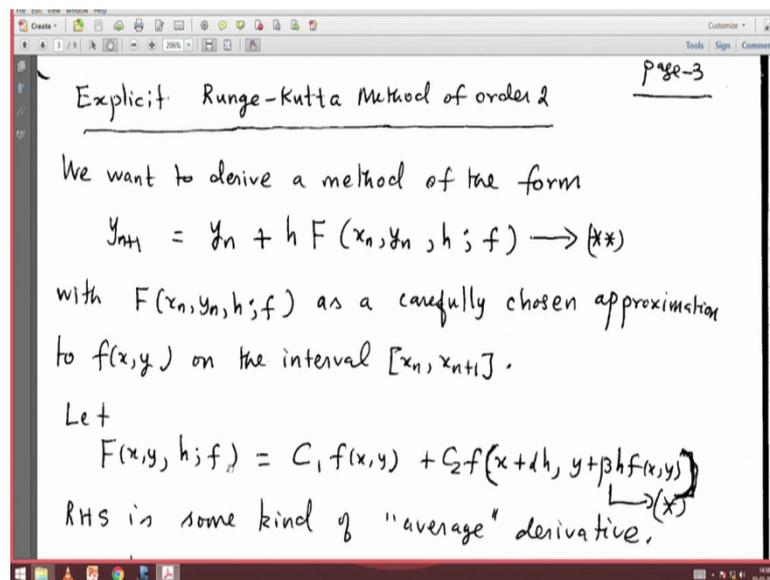

So these are the first set of terms involving first order partial derivatives what will be the next term 1×2 factorial into h^2 which corresponds to square of $(x - x_0)$ into f with respect to x twice plus $2 h k$ which is $(x - x_0) k$ which is $(y - y_0)$ into second order

derivative with respect to x with respect to y once right? And then $(y - y_0)$ the whole square into f second order derivative with respect to y twice.

That will constitute the terms involving second order derivatives and so on and now I have the term involving $1/n!$ all these terms constitute $p_n(x,y)$ which is called the n th polynomial Taylor polynomial in two variables for the function f about the point x_0, y_0 . And to this I should add $R_n(x,y)$ which is the remainder and this will involve $1/(n+1)!$ and terms involving the $(n+1)$ th derivative of f with respect to x with respect to y appropriately.

So this is Taylor expansion for a function of two variables about a point x_0, y_0 so we will make use of this in deriving Runge - kutta Methods of appropriate orders. So let us now move on to their derivation of this method.

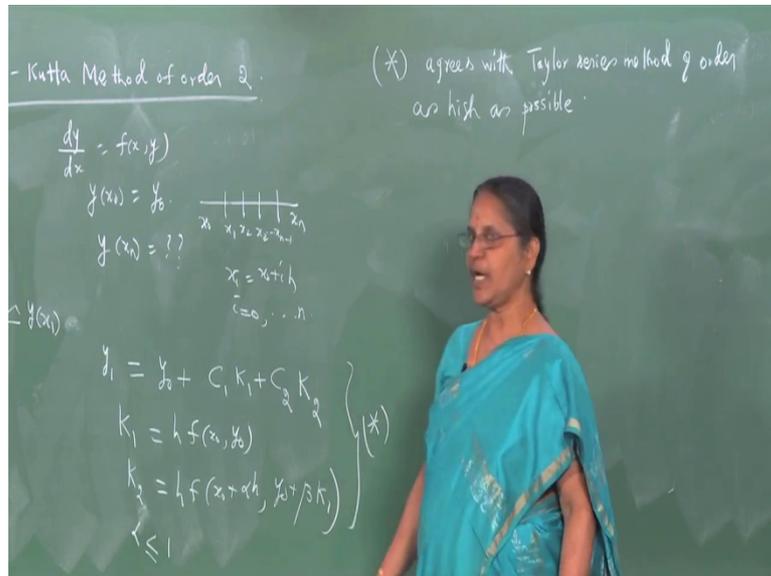

(Refer Slide Time: 09:45)

So first of all we shall derive Runge - kutta Method of order 2, so I will explain why we call this as a method of order 2 later on when we complete our derivation. It is an explicit method reason is that if we know the values of $y(x_1)$ say y_1 then we can march one step ahead which is at a distance of h units from x_1 namely I can go to the point x_2 and compute $y(x_2)$ namely y_2 explicitly with a knowledge that I have about the function y or $f(x,y)$ at the point x_1 .

And go ahead like this and determine the solution at each of these points explicitly and so it is referred to as an explicit method. So in Runge - kutta Method of order 2 what is it that we are interested in? So let us just look at the board to see what we want?

(Refer Slide Time: 10:55)

So we would like to derive RK method we call it as RK method Runge - kutta Method of order 2 and this method we solve a first order differential equation of the form dy by dx equal to $f(x,y)$ with $y(x_0)$ equal to y_0 and go upto the computation of our solution at x_n . So we have an interval x_0 to x_n which we divide into number of sub intervals of the form x_0 to x_1 to x_2 etc such that x_i is x_0 plus $i h$ for i is equal to $0, 1, 2, 3$ upto n .

So at the first step we would like to compute $y(x_1)$. This is approximated by y_1 , so y_1 approximates $y(x_1)$. And I would like to derive this method in such a way that $y(x_1)$ is going to y_0 plus some constant c_1 times k_1 plus c_2 times k_2 where c_1 and c_2 are constants to be determined and k_1 and k_2 are functions such that k_1 is h into $f(x_0, y_0)$ and k_2 is h into $f(x_0 + \alpha h, y_0 + \beta k_1)$. So you observe that k_1 involves evaluation of the function f which appears here at x_0, y_0 and we know both x_0 and y_0 so immediately this can be obtained.

And what is k_2 that again involves evaluation of the same function but now at a point $(x_0 + \alpha h, y_0 + \beta k_1)$ where again α and β are constants to be determined and where does this point where does this $x_0 + \alpha h$ lie we are computing the solution at x_1 namely y_1 .

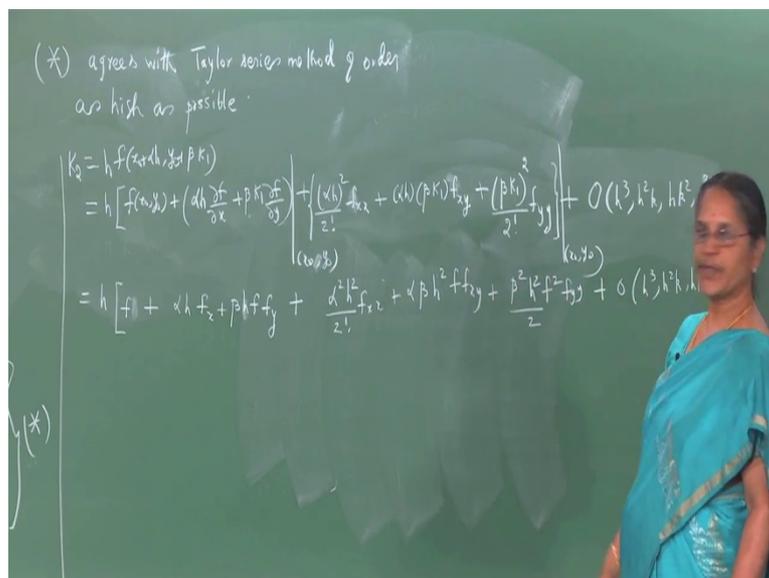

So I want this point $x_0 + \alpha h$ to be a point between x_0 and x_1 . So it's immediately clear that α is less than or equal to 1. This point can be x_1 also when α is 1. So I want the point to be somewhere between x_0 and x_n . Already I have taken the function value would x_0, y_0 . So I would like to evaluate this function at some point $x_0 + \alpha h$. I do not know what this α is now I have to determine not only α I also have to determine the constant β .

So we now have 4 constants c_1, c_2, α, β with the restriction that α must be less than or equal to 1 such that these 4 constants have to be evaluated. What is the condition with the help of which you are going to determine these constants. The condition is that the method that we have written so I call this as star right? This method star agrees with Taylor series method of order as high as possible.

Remember Taylor series method involves derivatives of certain functions but I can replace the derivatives in terms of the partial derivatives of f of different orders. On the other hand this method involves only the function evaluations at certain points in the interval x_0 to x_1 when you want your solution at x_1 knowing your solution at x_0 .

So the requirement is that the constant c_1, c_2, α, β must be determined in such a way that method star mimics or it agrees with Taylor series method of order as high as possible. So let us obtain what this star is and what is Taylor series method of order as high as possible that matches with this method star and then determine the constants c_1, c_2, α and β .

(Refer Slide Time: 16:17)

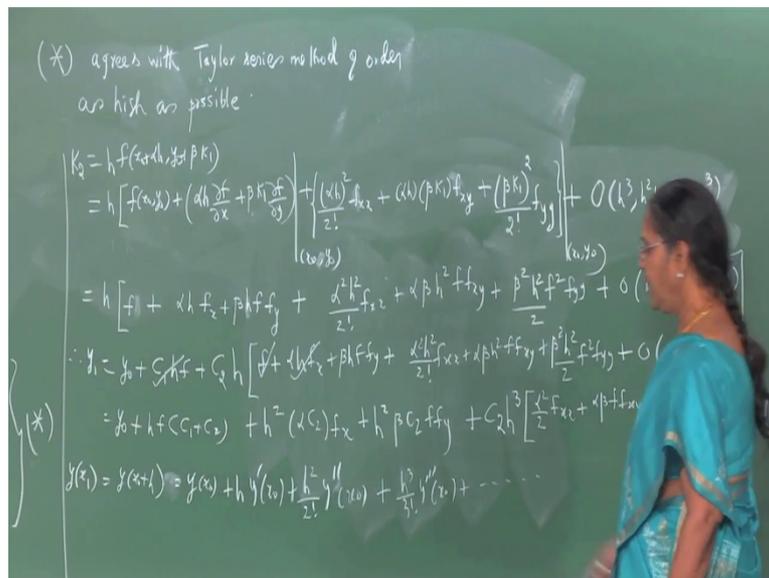

So let us first take $k=2$ so what is $k=2$? $k=2$ is h into $f(x_0 + \alpha h, y_0 + \beta h)$
 So I have a function of two variables and each variable is such that an increment is given to the first argument an increment is given to the second argument so I use Taylor's theorem for two variables and write this as $f(x_0, y_0) + \alpha h$ into partial derivative of f with respect to x plus βh into partial derivative of f with respect to y then I take αh the whole square by factorial 2 into f with respect to xx twice then $2 h k$ is the increment for h and k divided by factorial 2 so I simply have increment αh multiplied by increment βh into partial derivative of f with respect to x with respect to y .

And then the next term will be square of the increment given to the second variable what is the square of the increment given to the second variable? It is βh so βh the whole square divided by factorial 2 into f_{yy} that is the next term. So these constitute terms involving the second order derivatives, plus terms of order of h^3 $h^2 k$ and then $h k^2$ and k^3 . In case we require then we will write down let us see what happens as our computations are carried out.

So remember that terms on the right hand side all these have to be evaluated at the point x_0, y_0 . So let us simplify this further so h into $f(x_0, y_0)$ I shall simply write it as f remembering that it should be evaluated at x_0, y_0 in then the next term plus αh into f_x plus βh into f_y what is $k=1$ I already have $k=1$ as h into f . So I substitute $k=1$ is h into f multiplied by f_y and then I write down the next set of terms which give me $\alpha^2 h^2$ by factorial 2 f_{xx} plus $2\alpha\beta h^2$ into what is $k=1$ f_{xy} so that will give me h^2 square f_{xx} plus $2\alpha\beta h^2$ into f_{xy} plus $\beta^2 h^2$ into f_{yy} divided by 2 plus order of terms involving h^3 $h^2 k$ $h k^2$ and so on.

(Refer Slide Time: 19:50)

So this is what we get for $k=2$. So I shall substitute in this method, so we have therefore y_1 to be given by y_0 plus C_1 into k_1 is h into f plus C_2 into k_2 ; k_2 has been computed so k_2 is h into $[f$ plus $\alpha h f_x$ plus $\beta h f_y$ plus $\alpha^2 h^2$ by factorial 2 f_{xx} plus $\alpha \beta h^2$ square f_{xy} plus $\beta^2 h^2$ by 2 f_{yy} plus order of these terms that is k_2 .

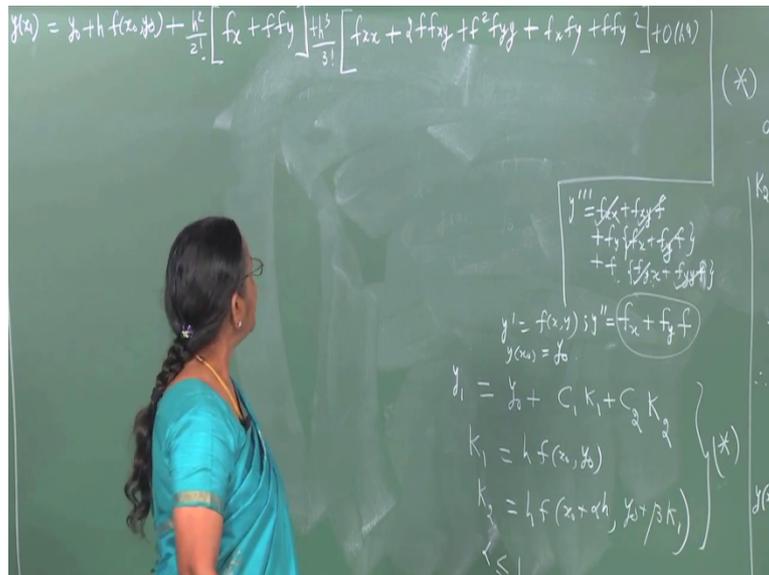

So which again can be simplified and written as y_0 plus h into f into C_1 plus C_2 . So we have these two terms then the next term is h^2 into αC_2 into f_x then the next term h^2 into βC_2 into f_y . Then I observe that the terms are C_2 into I have h^2 appearing in all the three h outside so I shall take C_2 into h^3 multiplied by write down the rest of the terms [α^2 by 2 f_{xx} plus $\alpha \beta$ f_{xy} plus β^2 by 2 into f_{yy}] that is the next set of terms.

And then I have terms now of what already I have h^3 h^2 h etc that must be multiplied by h so they will be all the of the order of h^4 h^3 h^2 h k square k square and h^3 k cube, so such terms will appear. So this is what our method is when we use Taylor expansion for a function of variables.

What is that we want? We want this method to agree upto Taylor series expansion upto order as high as possible. So let us write down the Taylor expansion namely I want to compute what is $y(x_1)$ which is $y(x_0 + h)$ because y_1 approximates $y(x_1)$. So I would like to get a Taylor expansion of y about the point x_0 .

So it is $y(x_0 + h)$ which is x_1 that will be equal to $y(x_0) + h$ into y' (x_0) plus h^2 by factorial 2 into y'' (x_0) plus h^3 by factorial 3 into y''' (x_0) plus etc this is Taylor series. So we shall now substitute for these derivatives and write down the solutions.

(Refer Slide Time: 23:36)

So we now write down what $y(x_1)$ is? So $y(x_1)$ will be equal to y_0 plus h into y' we know the differential equation is y' is equal to $f(x, y)$ and the initial condition is $y(x_0) = y_0$ and we want $y'(x_0)$ so it is f evaluated at (x_0, y_0) .

Then the next term h^2 by factorial 2 what do I have y'' when y' is $f(x, y)$ y'' is $d/dx (f(x, y))$ $f(x, y)$ is a function of two variables x and y , y itself is a function of x so it will be f with respect to x partially f with respect to the second argument y into y' with respect to x which will be y' and that y' is f .

So I know y'' now and I have to evaluate it at x_0 . so the next term will be h^2 by factorial 2 into y'' at x_0 . So it is $[f_x(x_0, y_0) + f_y f]$. Now let us go to the next term so I have h^3 by factorial 3 into I require the third derivative namely y''' . So we already have computed this third derivative in the previous class, let us work out the details.

So I need to get d/dx of this the term is a function of x and y and I require the derivative d/dx of this, so this is going to be the partial derivative of this with respect to x plus this with respect to y into y' with respect to x .

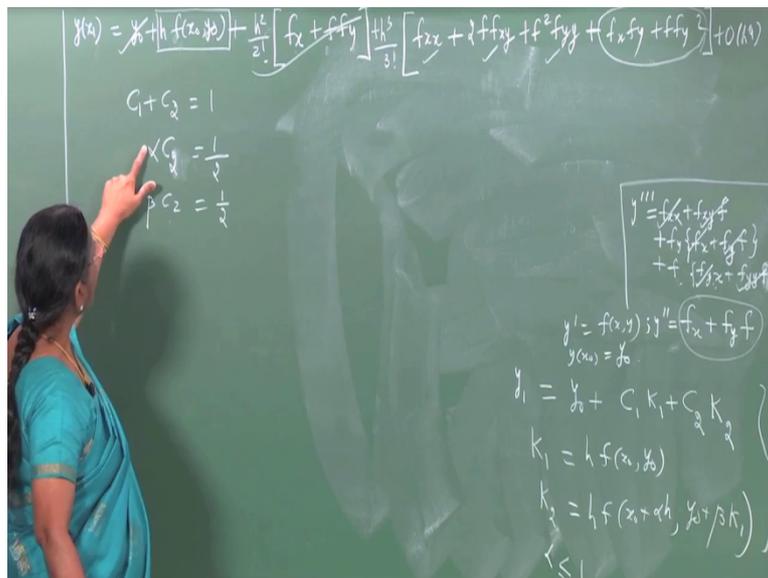

Now I apply the product rule right? Then partial derivative of f with respect to x f_x with respect to y into y with respect to x . Then the next term f into partial derivative of f_y with respect to x plus partial derivative of f_y with respect to y into y' that is f . So this will give you the third derivative so we shall substitute there so I have f_{xx} when I have f into f_{xy} and f into f_{yx} f being continuous the mixed partial derivatives are equal so I can combine this and write it as $2f$ into f_{xy} .

Then I have f^2 into f_{yy} so let me write that also and now we are left with the terms f_x into f_y which comes from here then f into f_y^2 which comes from here so we have taken into account all the terms. So plus order of h to the power of 4, So we have written down Taylor expansion about the point x_0 in terms of the partial derivatives of f and all these terms on the right hand side we have to be evaluated at x_0, y_0 similarly all the terms which appear in the method star which we have developed also have to be evaluated at x_0, y_0 .

We now enforce this condition; the method that we have derived here must match with Taylor series method which is written here upto order as high as possible. What is the maximum order of the Taylor series method with which the given method star which we are deriving will match. So let us look at the first term in y_1 here that is y_0 , in the Taylor expansion it is y_0 . So that is matched, move on to the next term.

I have a $h f$ into C_1 plus C_2 in the method that we are deriving and here we have a h into f so in order that these two match we must have C_1 plus C_2 to be equal to 1. If C_1 plus C_2 is equal to 1 then the term here is the same as the term in Taylor expansion. Fine we move on to the next term. So we take the coefficient of f_x here which is $h^2 \alpha C_2$ and we observe the corresponding term in the Taylor expansion.

(Refer Slide Time: 28:41)

We have h^2 by 2 into f_{xx} so if we equate the coefficient of $h^2 f_{xx}$ from both we get half to be equal to αC_1 ; αC_2 so αC_2 must be equal to half. Then we take the next term ff_{yy} into h^2 the coefficient is βC_2 and I have $ff_{yy} h^2$ and its coefficient is equal to half, so we have matched the coefficient of h^2 terms in both the methods.

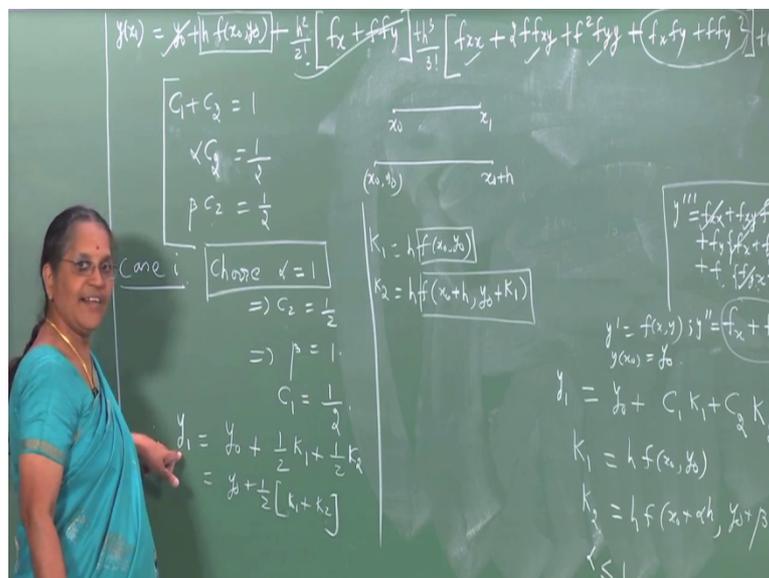

We now move on to the coefficient of h^3 term we observe that we have a f_{xx} term here as well as here f_{xy} term which appears in both of them f_{yy} that again appears in this term. These coefficients involve C_2 in it right? I can take the corresponding terms f_{xx} whose coefficient will be α^2 by 2 into C_2 and equate it to the corresponding coefficient here which is $1/3$ factorial I can do it for each of these terms but I observe that I have two extra terms alright which I cannot match with the method that I have because my method does not have that term in it.

One may say that if I choose my C_2 to be equal to 0 these terms do not appear at all. But I cannot make this C_2 to be 0 right? In that case what will happen when C_2 is 0 then we get inconsistent values here α into 0 will be half β into 0 will be half. So C_2 cannot be made 0 that is clear. So C_2 has to take a non zero value. So when C_2 takes a non zero value here because of the presence of these extra two terms I cannot match order of h^3 terms in the Taylor expansion with the order of h^3 terms in my method that is not possible.

So I can match the method that we are deriving namely star with the Taylor series method only upto order of h square term. That is the maximum order possible here is a Taylor series method of order 2 namely terms upto order of h square in Taylor series can be matched with the method that I am looking for namely star.

..So the h cube terms cannot be matched and that will be the first neglected term in the Taylor expansion. So I look at the equations which have helped us to match upto Taylor method of order 2. We observe that there are 4 constants c 1 c 2 alpha beta but there are only three equations so one of the constants can be arbitrarily chosen. So let us choose say alpha to be equal to 1.

(Refer Slide Time: 32:53)

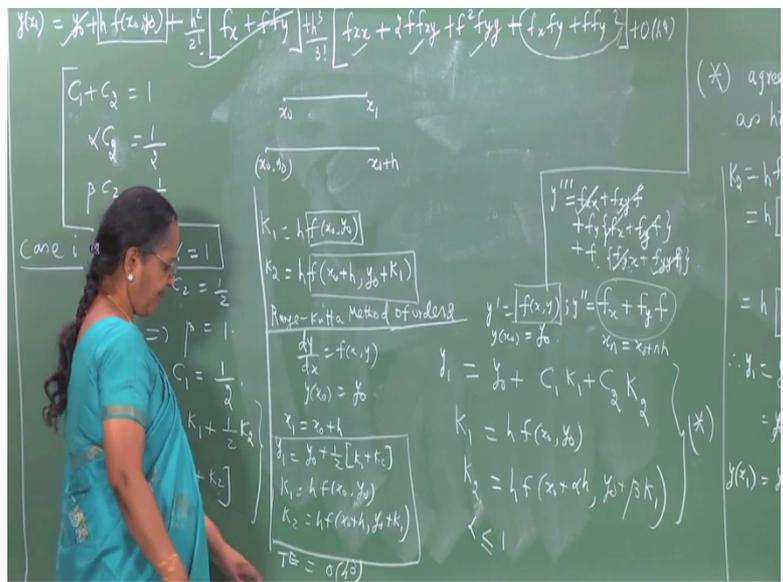

So let us choose alpha to be equal to 1 which will give you C 2 to be equal to half and therefore beta will be equal to 1. So when alpha is 1, beta 1 C 2 half and since C 1 plus C 2 is 1 is immediately gives you that C 1 is also equal to half. So we start with the choice namely alpha equal to 1 this is one way of choosing any one of the constant can be arbitrarily chosen such that consistent solution of this system can be obtained.

So this is the first case namely the choice has been made like this. So with this we obtain our method to be y 0 plus C 1 which is half into k 1 plus C 2 which is again half into k 2 or it is y 0 plus half (k 1 plus k 2). What are k 1 and k 2 we see that k 1 is h into f (x 0 y 0) and what is k 2 it is h into f (x 0 plus alpha h) what is alpha; alpha is 1 so plus h , y 0 plus beta k 1 beta is 1 so plus k 1.

So I have to evaluate the function where at the point x_0, y_0 and at the point which is this point? x_0 plus h and the corresponding y argument is y_0 plus k_1 and I know what k_1 is. But anyway since this will be some number k_1 is some number which represents a slope of a certain line right? And x_0 plus h will be a number what is this x_0 plus h is x_1 so when I start with the point with x_0 and move to x_1 what am I doing? I am considering k_1 to be h times a slope at x_0, y_0 and k_2 which is h times the slope at the point $x_1, y_0 + k_1$.

So I have two slopes and I am taking the average of these slopes k_1 and k_2 and adding it to y_0 to get the value of y_1 . It is a sort of an average of the slopes that is being taken and the method that we have derived is this with k_1 and k_2 given by this and we do not have any derivative evaluation of a function we simply evaluate a function f what is this function? The function f which appears on the right hand side of the given initial value problem at different points namely one of them is at x_0, y_0 the other one is x_1 at which we want the solution, $y_0 + k_1$ and k_1 is nothing but $h f(x_0, y_0)$. So we simply have to use this method and arrive at our solution at the point x_1 and what we get is an approximation to the solution $y(x_1)$ at the point x_1 .

(Refer Slide Time: 36:40)

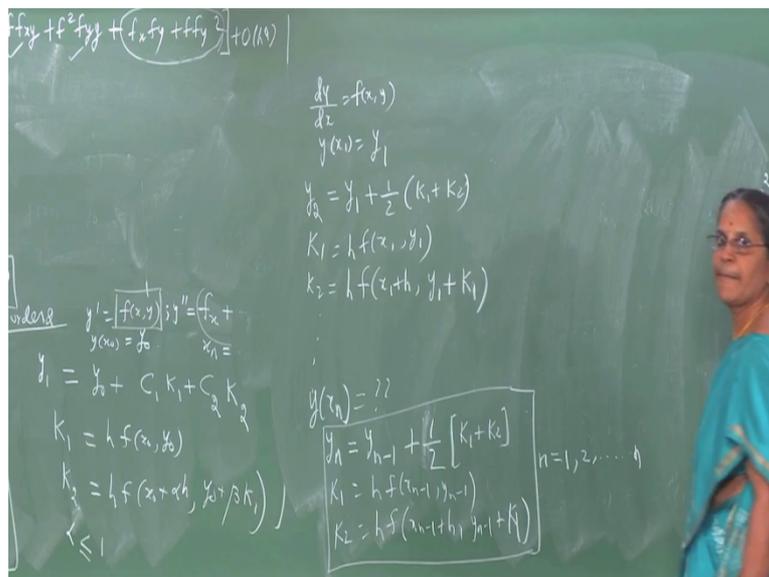

So we summarize and write down our Runge Kutta method which we have derived it is an explicit method it is a single step method so it solves the initial value problem $dy/dx = f(x, y)$ subject to $y(x_0) = y_0$ and when I require the solution say at the next point which is x_0 plus h then its solution is y_0 plus half of k_1 plus k_2 where k_1 is h into $f(x_0, y_0)$ and k_2 is h into $f(x_0 + h, y_0 + k_1)$.

So this is my method and what is the property of this method? This method matches with a Taylor series method of order 2 because upto h^2 term we have matched so it matches with Taylor series method of order 2. So when you consider Taylor series method of order 2 what is the truncation error it is of order of h^3 .

Since Runge Kutta Method matches with Taylor series method of order 2 we call this as Runge Kutta Method of order 2. Therefore what is the truncation error? The truncation error is the order of the first neglected term namely h^3 so the local truncation error of this method is going to be of order h^3 .

So we use Runge Kutta Method of order 2 to compute the solution at the first point x_1 by taking the step size h to be small the accuracy can be proved. Ok what was our goal? Our goal was to go upto the point x_n such that x_n is x_0 plus $n h$ we have just given the solution at x_1 .

(Refer Slide Time: 38:48)

So what do we do and solve the initial value problem dy by dx is equal to x is equal to $f(x, y)$ subject to the condition $y(x)$ equal to y_1 . What is this y_1 ? This y_1 is what we have already computed. And so what is the solution $y(x_2)$ is approximated by y_2 , and what is it? It is y_1 half of k_1 plus k_2 , and what are k_1 and k_2 ? K_1 is $h f(x_1, y_1)$ and k_2 is $h f(x_1 + h, y_1 + k_1)$.

So at every step you evaluate 2 functions the method involves just two function evaluations and the method is of order 2. So I can continue this and finally come to the solution at the

point x_n . So to get this we again apply RK method of order 2 and get y_n to be equal to $y_{n-1} + \frac{1}{2}(k_1 + k_2)$ and what are k_1 and k_2 ?

k_1 is $h f(x_{n-1}, y_{n-1})$ and k_2 is $h f(x_{n-1} + h, y_{n-1} + k_1)$. So if you apply this you obtain the solution at the point x_n or one can say that the solution of the initial value problem given by Runge Kutta method of order 2 is this for values of n equal to 1,2,3 etc upto n .

So when n is 1 y_1 is $y_0 + \frac{1}{2}(k_1 + k_2)$ with appropriate function values for k_1, k_2 , where n is 2 you get y_2 is $y_1 + \text{something}$ and continue this you end up with a solution at the point y_n . So explicitly you determine the solution at each of the nodes into which you have divided the entire interval into n equal sub intervals. And you go step by step to compute this solution, so it is a single step explicit method of order 2 and is called Runge Kutta method of order 2 matches with Taylor series method of order 2 and so it has truncation error of order h^3 .

So we now move on to higher order Runge Kutta methods but before that we will see whether there are any other possibilities so the derivation is presented here. I thought it will be easier to follow when I discuss it on the board and that is why we worked out the details on the board. But all these details are also available in the material that is displayed on the monitor.

(Refer Slide Time: 42:07)

high order as possible'

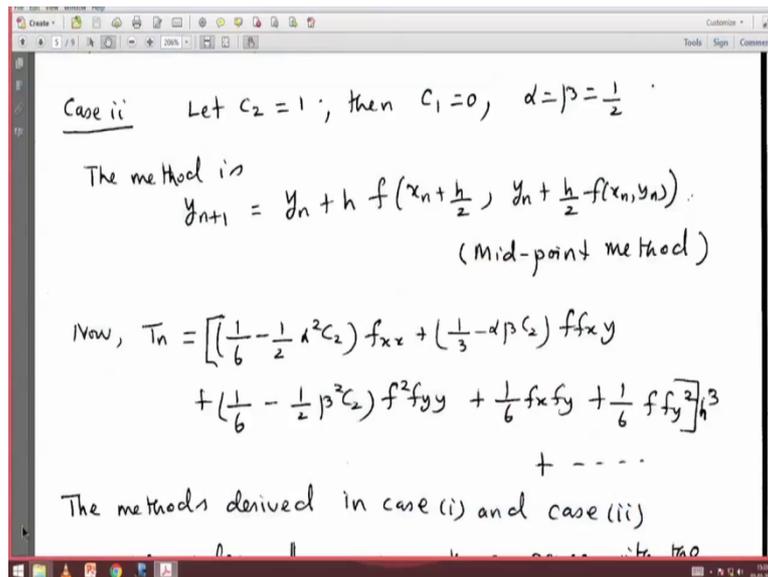

$$F(x, y, h; f) = C_1 f + C_2 \left[f(x, y) + \alpha h f_x + \beta h f_y \right. \\ \left. + \frac{1}{2!} \left[(\alpha h)^2 f_{xx} + 2(\alpha h)(\beta h) f_{xy} + (\beta h)^2 f_{yy} \right] + \dots \right]$$

$$= (C_1 + C_2) f + h \left[C_2 \alpha f_x + C_2 \beta f_y \right] \\ + \frac{h^2}{2!} \left[\alpha^2 C_2 f_{xx} + 2\alpha\beta C_2 f_{xy} + \beta^2 C_2 f_{yy} \right] + \dots$$

Substituting this in (**)

So if you look at Case 1 there we have chosen C_2 to be equal to half namely whatever that is given here has been considered and the RK Method of order 2 has been obtained. It is also known as modified Euler's Method and I shall explain the details of why it is called a modified Euler's Method later on, when I complete the discussion on the Runge Kutta Methods.

(Refer Slide Time: 42:40)

There is another possibility of solving this system of equations which we have written here namely $C_1 + C_2 = 1$; αC_2 is half and βC_2 is equal to half. So let us look at the monitor and see what are the choices. I can also make C_2 to be 1 in which case C_1 will be 0 and α and β will each be equal to half.

Then in that case I end up with a method which is y_{n+1} namely $y(x_{n+1})$ is $y_n + h$ into $f(x_n + \alpha h, y_n + \beta h)$ so $x_n + h/2$ then $y_n + h/2$ into $f(x_n, y_n)$. We call this as the midpoint method because we started with our initial condition at x_n we want to determine the solution at x_{n+1} .

We evaluate the function f at the midpoint which is $x_n + h/2$. So we call this as the midpoint method. And if you write down the truncation error in that method which is the difference in the order of h^3 term that appears in our method star minus the order of h^3 terms which appear in the Taylor expansion and that is what is presented as T_n in this material.

(Refer Slide Time: 44:14)

The method is

$$y_{n+1} = y_n + h f\left(x_n + \frac{h}{2}, y_n + \frac{h}{2} f(x_n, y_n)\right)$$

(Mid-point method)

Now, $T_n = \left[\left(\frac{1}{6} - \frac{1}{2} \alpha^2 \beta_2\right) f_{xx} + \left(\frac{1}{3} - \alpha \beta_2\right) f_{xy} \right. \\ \left. + \left(\frac{1}{6} - \frac{1}{2} \beta_2^2\right) f_{yy} + \frac{1}{6} f_x f_y + \frac{1}{6} f_y^2 \right] h^3 + \dots$

The methods derived in case (i) and case (ii) are of order two since these agree with the Taylor's method of order two.

The midpoint method that we derived is again a Runge Kutta method of order 2 because we have been able to match this method upto second order in Taylor expansion of the function and therefore its again a second order method.

(Refer Slide Time: 44:32)

Runge-Kutta method of order 4: $\frac{dy}{dx} = f(x, y), y(x_0) = y_0$ solve for y in $[x_0, x_n]$.

$$y_{n+1} = y_n + \frac{1}{6} [K_1 + 2K_2 + 2K_3 + K_4]$$

$$K_1 = h f(x_n, y_n)$$

$$K_2 = h f\left(x_n + \frac{h}{2}, y_n + \frac{1}{2} K_1\right)$$

$$K_3 = h f\left(x_n + \frac{h}{2}, y_n + \frac{3}{4} K_1 + \frac{1}{4} K_2\right)$$

$$K_4 = h f(x_n + h, y_n + K_3)$$

Note If $\frac{dy}{dx} = f(x)$, then RK method of order 4 gives

$$y_{n+1} = y_n + \frac{1}{6} [K_1 + 2K_2 + 2K_3 + K_4]$$

Now we move on to Runge Kutta method of order 4. Now it is clear when I say I want to move on to Runge Kutta method of order 4 it means that we would like to derive a method which involves four function evaluations and the method must match with Taylor series expansion upto order of h to the power of 4.

So we write down this method which solves this initial value problem $dy/dx = f(x,y)$ with $y(x_0) = y_0$. My method is going to be $y_{n+1} = y_n + h \left[\frac{1}{6} k_1 + \frac{4}{6} k_2 + \frac{2}{6} k_3 + \frac{1}{6} k_4 \right]$, where k_1, k_2, k_3, k_4 are function evaluations done at some intermediate points between x_n and x_{n+1} .

What is x_{n+1} ? That is $x_n + h$, what is $x_{n+1/2}$? That is a midpoint of this interval x_n to x_{n+1} . So function evaluations are done at points which lie between x_n and x_{n+1} . And it involves these 4 function evaluations k_1, k_2, k_3, k_4 and method which is given here is the fourth order method such that it agrees with the Taylor series method of order h to the power of 4.

Just one important observation we need to solve for y in the interval x_0 to x_{n+1} . So we divide the interval x_0 to x_{n+1} into $n+1$ equal parts by means of points $x_0, x_1, x_2, \dots, x_n, x_{n+1}$. So any x_n can be written as $x_0 + i h$ where i runs from 0 to $n+1$. That is why the solution given here as $y_{n+1} = y_n + h \left[\frac{1}{6} k_1 + \frac{4}{6} k_2 + \frac{2}{6} k_3 + \frac{1}{6} k_4 \right]$.

So we do not go into the details of the derivation of this method. Here the method has to be derived similar to what we have done in the derivation for second order method. So write down the method expand by Taylor series expansion for function of two variables. Now you have to go upto order of h to the power of 5 for our method.

Also write down Taylor series method of order h power 5 and then match that terms upto order of h power 4 in Taylor series method and also in our method then you will end up with the coefficients which appear here to be $\frac{1}{6}, \frac{2}{6}, \frac{1}{6}$ and $\frac{1}{6}$ which we can call as C_1, C_2, C_3, C_4 and also the coefficients that may appear here has coefficient of h as half coefficient of k_1 to be half.

Here again coefficient of h to be half, here 2 to be half and here it is 1 and the coefficient of k_3 is 1, so that the terms of Taylor series of method of order 4 agree with our method upto h to the power of 4 terms.

(Refer Slide Time: 48:15)

Handwritten notes on a digital whiteboard showing the formulas for the Runge-Kutta method of order 4. The equations are:

$$k_2 = h f\left(x_n + \frac{h}{2}, y_n + \frac{1}{2}k_1\right)$$

$$k_3 = h f\left(x_n + \frac{h}{2}, y_n + \frac{1}{2}k_2\right)$$

$$k_4 = h f(x_n + h, y_n + k_3)$$

Note: If $\frac{dy}{dx} = f(x)$, then RK method of order 4 gives

$$y_{n+1} = y_n + \frac{1}{6} [k_1 + 2k_2 + 2k_3 + k_4]$$

$$k_1 = h f(x_n)$$

$$k_2 = h f\left(x_n + \frac{h}{2}, y_n + \frac{1}{2}k_1\right) = h f\left(x_n + \frac{h}{2}\right)$$

$$k_3 = h f\left(x_n + \frac{h}{2}, y_n + \frac{k_2}{2}\right) = h f\left(x_n + \frac{h}{2}\right)$$

$$k_4 = h f(x_n + h, y_n + k_3) = h f(x_n + h)$$

So we essentially have derived Runge Kutta method of order 4. In particular I would like to see what happens if the right hand side $f(x,y)$ only depends on x there is no dependence of f on y , then in that case what does this Runge Kutta method of order 4 give. So it is $y_{n+1} = y_n + \frac{1}{6} [k_1 + 2k_2 + 2k_3 + k_4]$. But now k_1 will be $h f(x_n)$, k_2 will be $h f(x_n + \frac{h}{2})$, $y_n + \frac{1}{2}k_1$, k_3 will be $h f(x_n + \frac{h}{2})$, $y_n + \frac{k_2}{2}$, k_4 will be $h f(x_n + h)$, $y_n + k_3$.

What is this? $f(x_n + \frac{h}{2})$, $y_n + \frac{h}{2} f$, function of x,y is simply a function of x alone so this is essentially $h f(x_n + \frac{h}{2})$ similarly k_3 will be $h f(x_n + \frac{h}{2})$ and k_4 will be $h f(x_n + h)$. So we get $y_{n+1} = y_n + \frac{1}{6} [k_1 + 2k_2 + 2k_3 + k_4]$ which is $y_n + \frac{1}{6} [k_1 + 2k_2 + 2k_3 + k_4]$ plus k_2 which is $2 h f(x_n + \frac{h}{2})$, $2 k_3$ which is $2 h f(x_n + \frac{h}{2})$ and finally k_4 which is $h f(x_n + h)$.

(Refer Slide Time: 49:54)

The image shows a whiteboard with handwritten mathematical derivations. The equations are as follows:

$$k_3 = h f\left(x_n + \frac{h}{2}, y_n + \frac{k_2}{2}\right) = h f\left(x_n + \frac{h}{2}\right)$$
$$k_4 = h f\left(x_n + h, y_n + k_3\right) = h f\left(x_n + h\right)$$
$$\therefore y_{n+1} = y_n + \frac{1}{6} \left[h f\left(x_n\right) + 2 h f\left(x_n + \frac{h}{2}\right) + 2 h f\left(x_n + \frac{h}{2}\right) + h f\left(x_n + h\right) \right]$$
$$= y_n + \frac{h}{6} \left[f\left(x_n\right) + 4 f\left(x_n + \frac{h}{2}\right) + f\left(x_n + h\right) \right]$$

Which is Simpson's integration method.

~~The truncation error~~ $T_n(y) = C(x_n) h^5 + O(h^6)$

for a suitable function $C(x)$.

Local Truncation error is $O(h^4)$.

So you get y_{n+1} to be $y_n + I$ can remove this factor h from here so h by $6 f(x_n)$ plus 4 times $f(x_n + h/2)$ plus $f(x_n + h)$. And do you recall what this method is? This is essentially Simpson's integration method which divide the interval x_n to $x_n + h$ into two equal subintervals by when we want to apply Simpson's rule then the Simpson's rule for integration between x_n to $x_n + h$ tell us that it is equal to h by 6 into sum of the n ordinates plus 4 times the intermediate ordinates. And that is what appears here.

So Runge Kutta method of order 4 reduces to simply $y_{n+1} = y_n +$ a term which comes from the integration of $f(x,y)$ between x_n and $x_n + h$ by applying Simpson's one third rule to that integral. And the error in this case will be of order of h to the power of 5 .

(Refer Slide Time: 51:19)

Solve by R-K method of order 4.

$$\frac{dy}{dx} = x+y \quad ; \quad y(0) = 1.$$

Take $h = 0.1$ and find $y(0.2)$.

$$y_{n+1} = y_n + \frac{1}{6} [k_1 + 2k_2 + 2k_3 + k_4]$$

$$k_1 = h f(x_n, y_n)$$

$$k_2 = h f(x_n + \frac{h}{2}, y_n + \frac{k_1}{2})$$

$$k_3 = h f(x_n + \frac{h}{2}, y_n + k_2)$$

$$k_4 = h f(x_n + h, y_n + k_3)$$

$$f(x, y) = x + y$$

$$x_0 = 0$$

$$y_0 = 1$$

$$k_1 = h f(x_0, y_0) = (0.1) f(0, 1) = (0.1)(0+1) = 0.1$$

$$k_2 = h f(x_0 + \frac{h}{2}, y_0 + \frac{k_1}{2}) = (0.1) f(0 + \frac{0.1}{2}, 1 + \frac{0.1}{2})$$

$$= (0.1) [0.05 + 1.05] = 0.11$$

So we shall conclude this discussion by taking a simple example of RK method of order 4 and applying it to say this equation. $\frac{dy}{dx}$ is equal to $x + y$ $y(0)$ is 1. So I want to take h as 0.1 and would like to find out what is $y(0.2)$. So I write down this method I know $f(x, y)$ is $x + y$ x_0 is 0 y_0 is 1, so substitute in the expression for k_1, k_2, k_3, k_4 the values are given here.

(Refer Slide Time: 51:59)

$$k_1 = h f(x_0, y_0) = (0.1) f(0, 1) = (0.1)(0+1) = 0.1$$

$$k_2 = h f(x_0 + \frac{h}{2}, y_0 + \frac{k_1}{2}) = (0.1) f(0 + \frac{0.1}{2}, 1 + \frac{0.1}{2})$$

$$= (0.1) [0.05 + 1.05] = 0.11$$

$$k_3 = h f(x_0 + \frac{h}{2}, y_0 + k_2) = h f(0 + \frac{0.1}{2}, 1 + \frac{0.11}{2})$$

$$= (0.1) [0.05 + 1.055] = 0.1105$$

$$k_4 = h f(x_0 + h, y_0 + k_3) = (0.1) f(0 + 0.1, 1 + 1.105)$$

$$= (0.1) [0.1 + 1.105] = 0.12105$$

$$\therefore y_1 = y(0.1) = y_0 + \frac{1}{6} [k_1 + 2k_2 + 2k_3 + k_4]$$

$$= 1 + \frac{1}{6} [0.1 + 2(0.11) + 2(0.1105) + 0.12105]$$

$$= 1.11034$$

Evaluate k_1, k_2, k_3, k_4 and then substitute in the method. So you get y_1 to be equal to 1.11034.

(Refer Slide Time: 52:11)

Now $y_2 = y_1 + \frac{1}{6} [k_1 + 2k_2 + 2k_3 + k_4]$

$k_1 = hf(x_1, y_1) = (0.1)f(0.1, 1.11034) = (0.1)[0.1 + 1.11034] = 0.121034$

$k_2 = hf(x_1 + \frac{h}{2}, y_1 + \frac{k_1}{2}) = (0.1)f(0.1 + \frac{0.1}{2}, 1.11034 + \frac{0.121034}{2}) = (0.1)[0.15 + 1.11034 + 0.060517] = 0.13208$

$k_3 = hf(x_1 + \frac{h}{2}, y_1 + \frac{k_2}{2}) = (0.1)f(0.1 + \frac{0.1}{2}, 1.11034 + \frac{0.13208}{2}) = (0.1)[0.15 + 1.11034 + 0.06604] = 0.132638$

$k_4 = hf(x_1 + h, y_1 + k_3) = (0.1)f(0.1 + 0.1, 1.11034 + 0.132638) = (0.1)[0.2 + 1.11034 + 0.132638] = 0.1442978$

$\therefore y_2 = 1.11034 + \frac{1}{6} [k_1 + 2k_2 + 2k_3 + k_4] = 1.2428 = y(0.2)$

And then start with the method and with the initial condition $y(x=1)$ is y_1 given by 1.11034 obtain y_2 namely $y(0.2)$. Let me y_1 plus 1 by 6 into k_1 plus $2k_2$ plus $2k_3$ plus k_4 . Again evaluate k_1 k_2 k_3 k_4 by substituting these values and you get y_2 to be equal to 1.2428.

(Refer Slide Time: 52:43)

Remark The main computational effort in using RK methods in the evaluation of f .

RK method of order 2. Local TE is $O(h^2)$
The cost is two function evaluations per step.

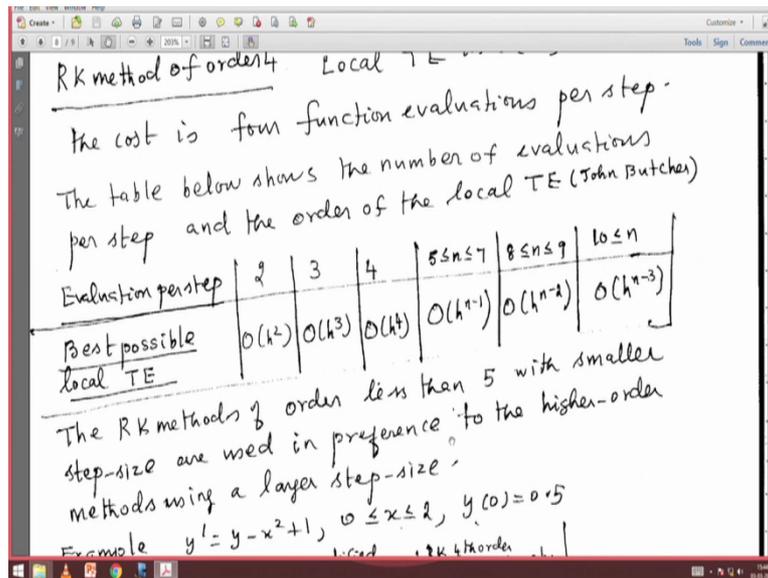

RK method of order 4. Local TE is $O(h^4)$
The cost is four function evaluations per step.

The table below shows the number of evaluations per step and the order of the local TE (John Butcher)

1	2	3	4	5 ≤ n ≤ 7	8 ≤ n ≤ 9	10 ≤ n
---	---	---	---	-----------	-----------	--------

So the main computational effort in using RK method lies in the evaluation of the functions f . So the local truncation error in a second order method is of order of h square the cost is just two function evaluations plus step. And an the method of order 4 it is order of h to the power of 4.

(Refer Slide Time: 53:11)

So the table below shows you the number of evaluations per step that you require when you consider the order of local truncation error. This was given by John Butcher. So you observe that in the second order evaluation of function per step when you use a second order method the best possible local truncation error is of order of h square.

If it is 3 then truncation error is of order of h cube and so on. But you observe that as the order of the method increases which lies between 5 or 7 or 8 or 9 or n greater than or equal to 10 the best possible truncation error that you obtain is only of order of h to the power of n minus 3.

So when n is equal to 10 you only end up with a method whose truncation error is of order of h to the power of 10 minus 3 namely h to the power of 7. So the RK methods of order less than 4 with smaller step size are preferable to higher order RK methods using a larger step size.

(Refer Slide Time: 54:31)

Methods using a x y

Example $y' = y - x^2 + 1$, $0 \leq x \leq 2$, $y(0) = 0.5$

x	Exact	Euler $h_1 = 0.025$	Modified Euler $h_2 = 2h_1$	RK 4th order $h = 0.1 = 4h_1 = 2h_2$
0.0	0.5000000	0.5000000	0.5000000	0.5000000
0.1	0.6574145	0.6554982	0.6573085	0.6574144
0.2	0.8292986	0.8253365	0.8290778	0.8292983
0.3	1.0150706	1.0089334	1.0147264	1.0150701
0.4	1.2140877	1.2056345	1.2136079	1.2140869
0.5	1.4256394	1.4147264	1.4250141	1.4256384

results are compared at the common mesh points
 Each of these methods requires 20 function evaluations
 to determine the values presented in the table.
 The RK method of order 4 is superior.

So the values of the function y which are solutions to this differential equation subject to initial condition by various methods are presented, namely Euler's method and then Runge Kutta method of fourth order and modified Euler's method which is nothing but Runge Kutta method of order 2. They have been presented at a set of points. And the RK method of order 4 seems to be superior to the other two methods.

So in practical applications one uses Runge Kutta method of order 4 in solving initial value problems which are governed by the first order differential equations. So we conclude this topic on Runge Kutta methods which are single step explicit methods and in the next class we shall try to derive methods which are known as Predictor Corrector Methods namely there is an opportunity for us to Predict the solution of an initial value problem and this predicted value can be corrected and successively re corrected till the desired degree of accuracy is reached. So we shall look into the details in the next class.
