Singular Value Decomposition (SVD)
Lecture – 41
Singular Value Decomposition (SVD) with SageMath

(Refer Slide Time: 00:15)

The screenshot shows a SageMath 9.1 JupyterLab window. The main content area displays a slide titled "Singular Value Decomposition (SVD)". The slide text reads: "Theorem (SVD) Let A be a real $m \times n$ matrix. Then there exist orthogonal matrices U and V such that $A = U \Sigma V^T$ where U is $m \times m$ orthogonal matrix, V is $n \times n$ orthogonal matrix and Σ is a $m \times n$ diagonal matrix whose diagonal entries are non negative and are arranged in a non increasing order. The number of non zero entries in Σ is the rank of A . Let $U = [u_1 \ u_2 \ \dots \ u_m]$, $V = [v_1 \ v_2 \ \dots \ v_n]$ and

$$\Sigma = \begin{bmatrix} \sigma_1 & 0 & \dots & 0 & 0 & \dots & 0 \\ 0 & \sigma_2 & \dots & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots & 0 & \dots & \vdots \\ 0 & 0 & \dots & \sigma_r & 0 & \dots & 0 \\ \hline 0 & 0 & \dots & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 & 0 & \dots & 0 \end{bmatrix}$$

The interface also shows a video feed of Prof. Ajit Kumar in the bottom right corner and a Windows taskbar at the bottom.

Welcome to the 41st lecture on Computational Mathematics with SageMath. In this lecture, we will look at a very important concept known as Singular Value Decomposition of a matrix.

In short, we write this as SVD. This SVD has several applications in science and engineering.

So, let us start with, what do I mean by this Single Value Decomposition. Let me state the result. Suppose, you have a matrix A , which is a real m cross n matrix and, then it says that you can find orthogonal matrices U and V such that; A can be written as U into σ times V transpose.

Here, U and V are orthogonal matrices and σ is a rectangular matrix, but it is a diagonal matrix and these non-zero entries of σ are arranged as decreasing order of the magnitude.

Let us let us see what do I mean by that. Here U, you can denote it by let us call a matrix u_1, u_2, \dots, u_m and since U is orthogonal, these u_1, u_2, \dots, u_m will be orthonormal set of vectors.

Similarly, V, we can denote it by v_1, v_2, \dots, v_n , and sigma is given by $\sigma_1, \sigma_2, \dots, \sigma_r$ and then all zeros. Here r is the rank of the matrix.

So, in case rank is r, the only non-zero entries will be σ_1 to σ_r and this σ_1 is bigger than equal to σ_2 , σ_2 is bigger than equal to σ_3 and so on.

This is what you have as a non-zero diagonal matrix. The remaining all entries are 0. That is how this sigma, U and V look like. Here the $\sigma_1, \sigma_2, \dots, \sigma_r$ are also known as singular values of A, and the number of singular values of A is nothing but the rank of this matrix A.

(Refer Slide Time: 02:23)

The screenshot shows a SageMath 9.1 notebook with the following content:

$$\Sigma = \begin{pmatrix} \sigma_1 & & & & & \\ & \sigma_2 & & & & \\ & & \dots & & & \\ & & & \sigma_r & & \\ & & & & 0 & \dots \\ & & & & & \dots \\ & & & & & & 0 & \dots \\ & & & & & & & \dots \\ & & & & & & & & 0 & \dots \\ & & & & & & & & & \dots \\ & & & & & & & & & & 0 & \dots \\ & & & & & & & & & & & \dots \\ & & & & & & & & & & & & 0 & \dots \\ & & & & & & & & & & & & & \dots \\ & & & & & & & & & & & & & & 0 & \dots \end{pmatrix}$$

- We have $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r$, are singular values of A. Here r is the rank of A.
- Note that $A^T A$ and $A A^T$ both are symmetric and hence are diagonalizable.
- $x^T A^T A x = (A x)^T (A x) = \|A x\|^2 \geq 0$. That is, $A^T A$ is symmetric and non-negative definite. Similarly, $A A^T$ is also symmetric and non-negative definite.
- ...
- ...
- ...

Now, let us play with this singular value decomposition. A is equal to U into sigma into V transpose. Suppose we look at what happens to A transpose A and A A transpose.

Notice that both A transpose A and A A transpose are symmetric matrices and therefore, it will be diagnosable. Not only that, if you look at for any vector x, x transpose A transpose A x.

(Refer Slide Time: 03:02)

The screenshot shows a SageMath 9.1 window with a matrix:

$$\begin{bmatrix} \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \dots & 0 & 0 & \dots & 0 \end{bmatrix}$$

Below the matrix, the text reads:

- We have $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r$, are singular values of A . Here r is the rank of A .

A note box contains the following text:

Note that $A^T A$ and $A A^T$ both are symmetric and hence are diagonalizable.
 $\langle A^T A x, x \rangle = \langle A x, A x \rangle = \|A x\|^2 \geq 0$. That is, $A^T A$ is symmetric and non-negative definite. Similarly, $A A^T$ is also symmetric and non-negative definite.

(Refer Slide Time: 03:07)

The screenshot shows the same SageMath 9.1 window with additional text:

- Note that $A^T A$ and $A A^T$ both are symmetric and hence are diagonalizable.
- $\langle A^T A x, x \rangle = \langle A x, A x \rangle = \|A x\|^2 \geq 0$. That is, $A^T A$ is symmetric and non-negative definite. Similarly, $A A^T$ is also symmetric and non-negative definite.

Then it states: "If $A = U \sum V^T$, then"

$$A^T A = (U \sum V^T)^T (U \sum V^T) = V (\sum^T \sum) V^T.$$

That is

$$V^T (A^T A) V = \sum^T \sum = \text{diag}(\sigma_1^2, \dots, \sigma_r^2, 0, \dots, 0)_{\text{non}}$$

Thus columns of V are eigenvectors of $A^T A$ with eigenvalues $\sigma_1^2, \dots, \sigma_r^2, 0, \dots, 0$.

So, this would be $A^T A$ this is nothing but inner product of $A^T A x$ with x which is same as saying inner product $A x$ with $A x$, that is nothing but norm of $A x$ square, which is always non-negative. So, for any vector x , what we have, $x^T A^T A x$ is always non-negative. That is same as saying, $A^T A$ is actually a symmetric and non-negative definite matrix. In particular, all eigenvalues of $A^T A$ will be non-negative. Similarly, you can check the other one. Let us say $y^T A A^T y$, that also you can check.

Now, let us look at. Suppose A is equal to U into σ into V transpose. Then if we compute A transpose A , then just replace the formula for A , what you get is this, This is nothing but V into σ transpose σ into V transpose. Now, what does it say? If you just multiply by V inverse on the left hand side and, then V on the right hand side, since V is orthogonal, V inverse is nothing but V transpose. So, what you have is, V transpose A transpose A into V is σ transpose σ . But σ transpose σ is actually nothing but a diagonal matrix σ_1 square, σ_2 square up to σ_m square and then, all the remaining 0's. This is m cross m diagonal matrix. That means, the A transpose A is diagonalized using V , that is same as saying the columns of V which are v_1, v_2, v_m are nothing but eigenvectors of A transpose A , with eigenvalues σ_1 square, σ_2 square and so on.

Then, take the square root of the σ_1 square, σ_2 square, non-negative square root of these, that is how you obtain this matrix σ .

(Refer Slide Time: 05:24)

The screenshot shows a JupyterLab window with the following content:

- Browser address bar: localhost:8888/lab
- File menu: File Edit View Run Kernel Tabs Settings Help
- Code editor: CSM_Lecture6-7.ipynb
- Mathematical derivations:
 - $AA^T = (U \sum V^T) (U \sum V^T)^T = U (\sum \sigma_i^2) U^T.$
 - That is
 - $U^T (AA^T) U = \sum^T \sum = \text{diag}(\sigma_1^2, \dots, \sigma_m^2, 0, \dots, 0)_{\text{local}}.$
 - Thus columns of U are eigenvectors of AA^T with eigenvalues $\sigma_1^2, \dots, \sigma_m^2, 0, \dots, 0.$
- Code block:

```
[2]: ## Example
[4]: A = matrix(RDF, [[1,2,3],[4,5,6]])
      U,S,V = A.SVD()
```
- Output:

Similarly you can look at what happens if you calculate A into A transpose. When you calculate A into A transpose, what you will get is; U into σ σ transpose U transpose. Therefore, you transpose A A transpose U is nothing but diagonal matrix σ_1 square, σ_2 square up to σ_n square and remaining all 0, this is n cross n

diagonal matrix which has only r non-zero entries. That means that the columns of U are eigenvectors of $A A^T$ with eigenvalues $\sigma_1^2, \sigma_2^2, \dots, \sigma_r^2$. Therefore, in order to find U and V , all we need to do is we need to find these eigenvectors of $A A^T$ and $A^T A$.

Eigenvectors of $A^T A$ are nothing, but columns of V . Eigenvectors of $A A^T$ are nothing but what column vectors of U . Of course, you need to find eigenbasis of $A A^T$ and $A^T A$ and that eigen bases will be actually the columns of U and V . Also, since $A A^T$ and $A^T A$ are symmetric matrices, eigenvectors corresponding to distinct eigenvalues will all be orthogonal. That is why we are able to find U and V which are orthogonal matrices with this property. So, this is a very simple concept and actually the proof of this theorem is also very easy. This is actually a constructive proof.

You simply need to start with eigenvectors of $A^T A$ and then, accordingly you define vectors u_i right. So, if you are interested to look at the proof of this result, you can look at any standard book on applied linear algebra.

Now, let us take an example. Suppose we have a matrix A , and since we wanted singular value decomposition that involves finding eigenvalues, eigenvectors, you may have to find numerical eigenvalues, eigenvectors. So, we will take the domain as \mathbb{R}^2 . So, the matrix is $\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$. So, that is the matrix. This is a rectangular matrix and it has rank 2.

So, let us see. Sage has inbuilt method to find singular value decomposition. All you need to do is, `A.svd()` in an empty round bracket.

(Refer Slide Time: 08:25)

```

[4]: A = matrix(RDF, [[1,2,3],[4,5,6]])
      U,S,V = A.SVD()

[5]: show(U)
      show(S)
      show(V)

```

$$\begin{pmatrix} -0.38631770311861147 & -0.9223657800770585 \\ -0.9223657800770585 & 0.38631770311861147 \\ 9.508032000695724 & 0.0 \end{pmatrix}$$

$$\begin{pmatrix} 0.0 & 0.7728696356734844 & 0.0 \\ -0.4286671335486261 & 0.8059639085892976 & 0.40824829046386285 \\ -0.5663069188480352 & 0.11238241409659372 & -0.816496580927726 \\ -0.7039467041474441 & -0.58119908039611 & 0.40824829046386313 \end{pmatrix}$$

Let us compute this and let us ask it to show what are the U S and V, I am denoting it by S. This is the matrix U, which is a 3 cross 3 matrix namely. Notice that A is 3 by 2 matrix and therefore, and this is the sigma, is actually 2 cross 3 matrix.

And these are the diagonal entries, this is going to be actually the square root of the eigenvalues of A A transpose or A transpose A and this is the second one.

And also, you can see here this is arranged in decreasing order. This is the maximum eigenvalue, this is the smallest one and this is V. V will be 3 cross 3.

(Refer Slide Time: 09:20)

```

```

And you can check that, U and V , what we have obtained are orthogonal matrices. So, if I look at U into U transpose, that should give be identity matrix. Similarly, if I look at V into V transpose, that should also be identity matrix. Of course, you can see here, this entry is of the order 10 to the power minus 6 which is as good as 0 . This is 10 to the power minus 7 , which is as good as 0 .

```

So, U and V are orthogonal matrices. Next, let us look at how we can obtain this manually. First, we need to compute A transpose A . Let me denote A transpose A as ATA and once we have ATA defined this. Let us find eigenmatrix of A transpose A . So, eigenmatrix will give you two matrices.

One is the diagonal matrix, since this matrix is diagonalizable, this will be the matrix D whose entries are eigenvalues. So, this is a sigma 1 square, this is sigma 2 square, this is sigma 3 square, this is 0. this is the matrix of eigenvectors. Similarly, you can find out A into A transpose and find out eigenmatrix of A into A transpose.

```

So, this is what you get. This is the diagonal entries, these are the eigenvalues. Of course, here it need not be arranged in decreasing order of eigenvalues, but this is what you get. Now, you have to interchange this to two columns.

You can just try to compare what we have obtained eigenmatrix in this case and what we obtained using the inbuilt function. You can see here, this this first column is same as first column of V, which we obtained using inbuilt function and the second column and third column will also be the same.

```

So, next let us look at what is geometric meaning of the singular value decomposition. You see A is a linear transformation. If A is m cross n matrix, A is a linear transformation from \mathbb{R}^n to \mathbb{R}^m . We would like to know how any object gets transformed by this matrix A .

For example, if I take any vector what happens to that vector. Since A is split as U into σ into V transpose, A of any object will be U times σ times V transpose. Now, U and V are actually orthogonal matrices and orthogonal matrices are nothing but actually matrix of rotation.

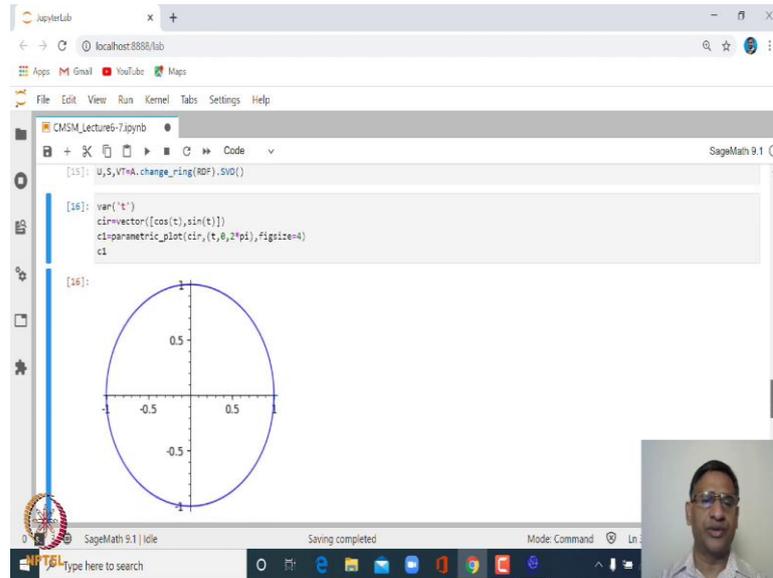

What V transpose will do? It will rotate that vector and σ is a diagonal matrix basically. So, that is going to do what? It is going to scale in each coordinate direction and then you rotate by U . So, any action of A onto any vector can be obtained as the sequence of action by V transpose σ and U transpose.

That gives you actually geometry, how an object changes by a matrix A .

Let us try to demonstrate this in 2-Dimension and 3-Dimension. Suppose you have a matrix. Let us look at this. This example we have already seen. Let us go back to this place. We have a matrix A which is 2 by 2 matrix $\begin{pmatrix} 4 & 2 \\ 2 & 3 \end{pmatrix}$, this is a symmetric matrix.

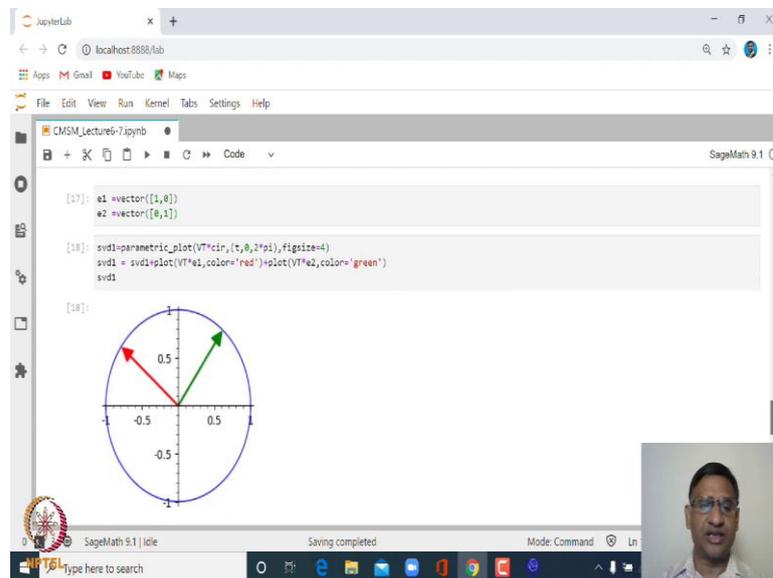

Now, let us find singular value decomposition of A . First we need to change the ring to \mathbb{R}^{DF} and find singular value decomposition of this. Now, let us see, suppose we have a unit circle.

(Refer Slide Time: 13:59)

We want to see what happens to a unit circle, when you apply A to it. What happens to the image of unit circle under A ?

(Refer Slide Time: 14:08)

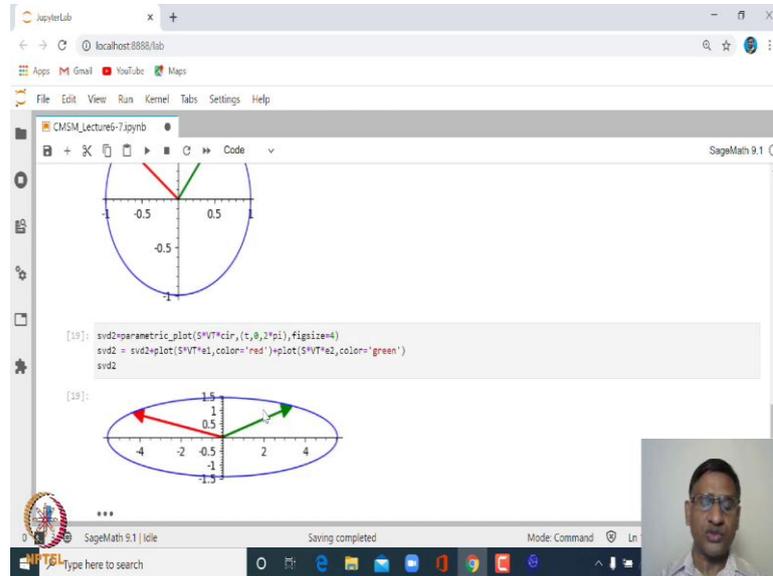

We want to see what happens to a unit circle, when you apply A to it. What happens to the image of unit circle under A .

Let us also plot these unit vectors e_1 and e_2 and then, let us plot this circle with the image of unit vectors. This is u_1 , this is e_2 . When you have multiplied this unit vectors by V transpose, V transpose u_1 and V transpose e_2 , then these vectors.

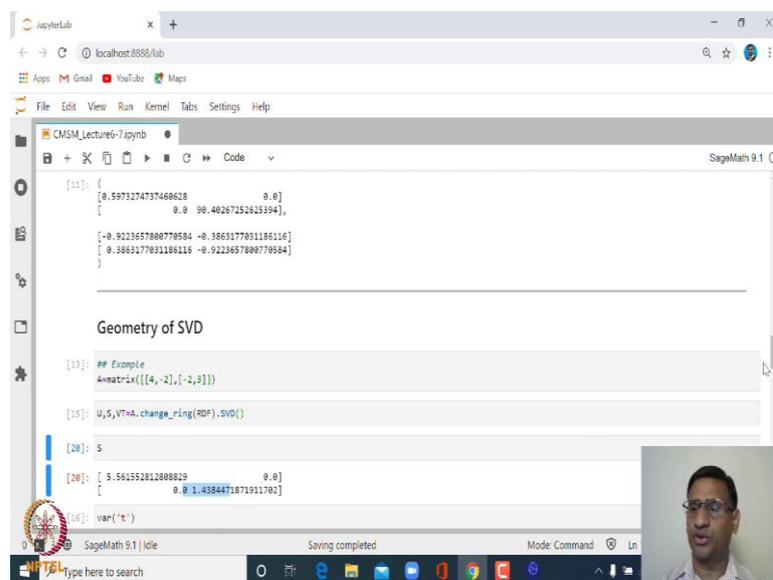

So, for example, this V transpose u_1 , is in red colour. So, u_1 goes to this, and e_2 goes to this. Actually you can check that this has been obtained using some kind of rotation.

(Refer Slide Time: 14:58)

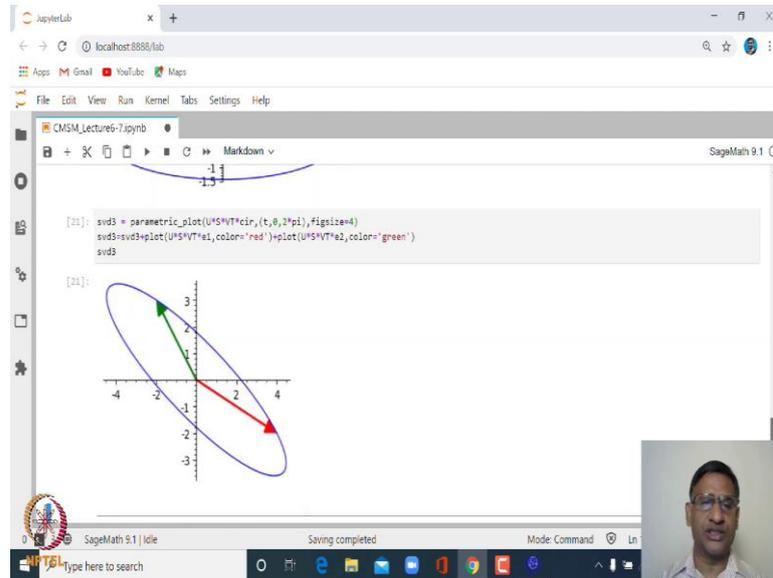

Now, next let us apply sigma to it. We applied V transpose into circle and then S into V transpose the circle. That is how the circle will change and also let us plot the vector S into V transpose e_1 and S into V transpose e_2 . When you plot this, you see what happens. This two e_1 and e_2 are scaled. So, for example, it is scaled by which factor?

(Refer Slide Time: 15:34)

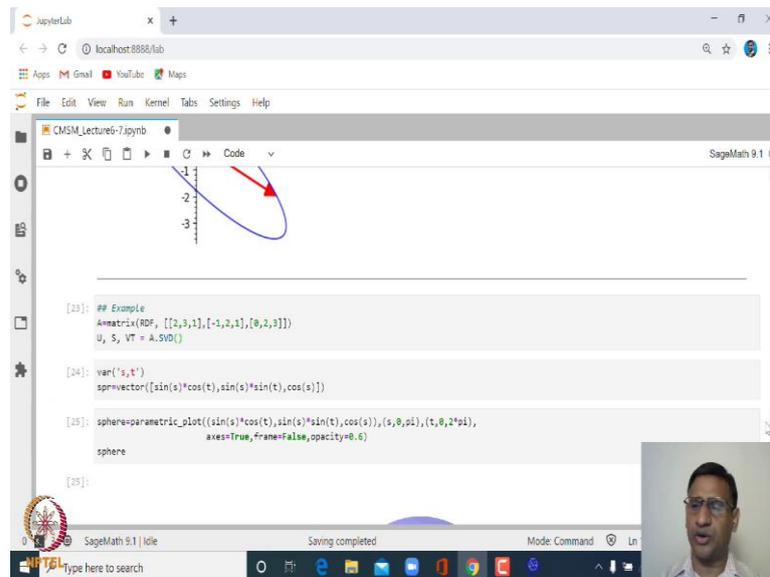

That we can obtain using this S . In this case S is this. So, first x -coordinate will be scaled by a factor of 5.56, the other coordinate is scaled by a factor of 1.43. That is exactly what has happened to these unit vectors right. So, the circle has become a kind of ellipse.

(Refer Slide Time: 16:03)

And now again applied U to it. So, when we apply U to it you will get some kind of rotation. So, U into S into V transpose of circle. Here again to u_1 apply A , which is same as saying U into S into V transpose. Similarly, U into S into V transpose of e_2 . So, that is how you get. So, now this ellipse is rotated like this by U . This is what it means actually. So, when you take any circle and apply A to it, this would become a kind of ellipse, this is the semi-major and semi minor axes, this will get rotated by once by V transpose and other one by U .

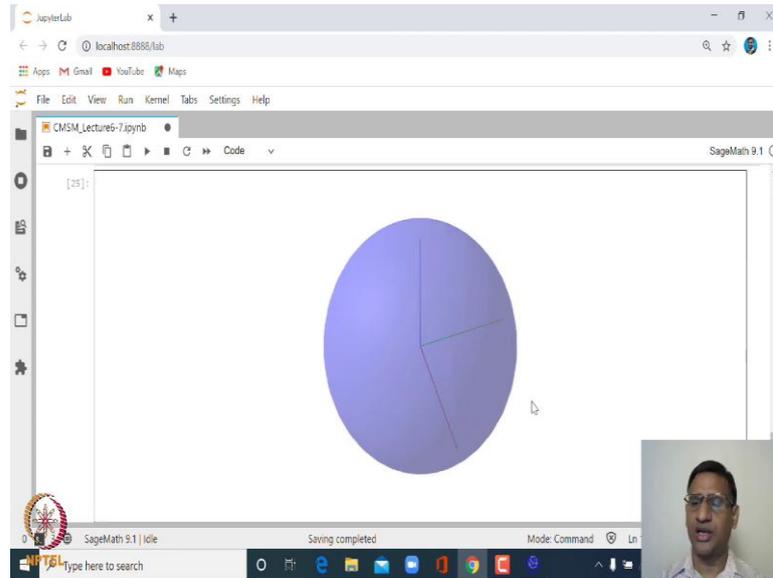

(Refer Slide Time: 16:56)

Similarly, you can do the same thing using 3 cross 3 matrix. Now, let us take a 3 cross 3 matrix 2, 3, 1 minus 1, 2, 1 and 0, 2, 3 and find out again singular value decomposition of A. $U S V^T$ which is V^T as A into $A \cdot SVD$ and let us take a sphere.

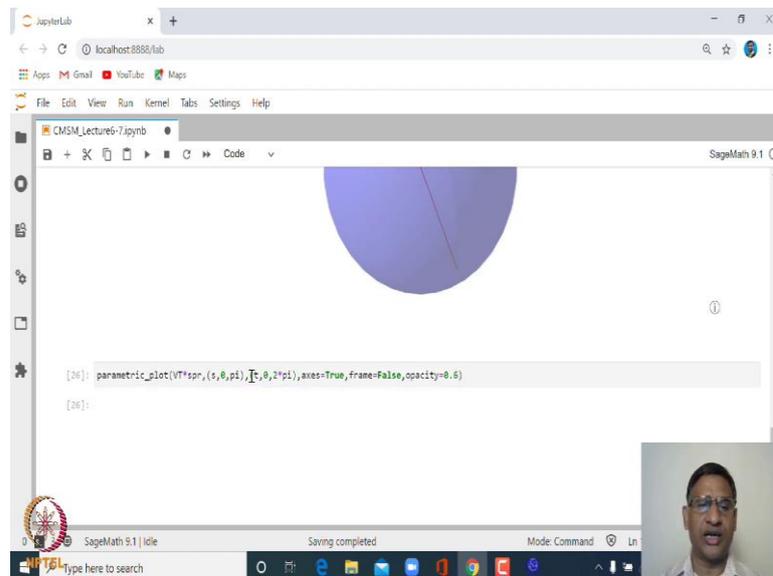

The parametric co-ordinate of a sphere is nothing but the first co-ordinate is $\sin s \cos t$ second co-ordinate is $\sin s \sin t$ and third coordinate is $\cos s$. Here, s and t will vary between 0 to 2π or other way round ok. So, let us plot. So, actually in this case s varies between 0 to π and t varies between 0 to 2π . So, let us plot this sphere as a parametric plot.

(Refer Slide Time: 17:55)

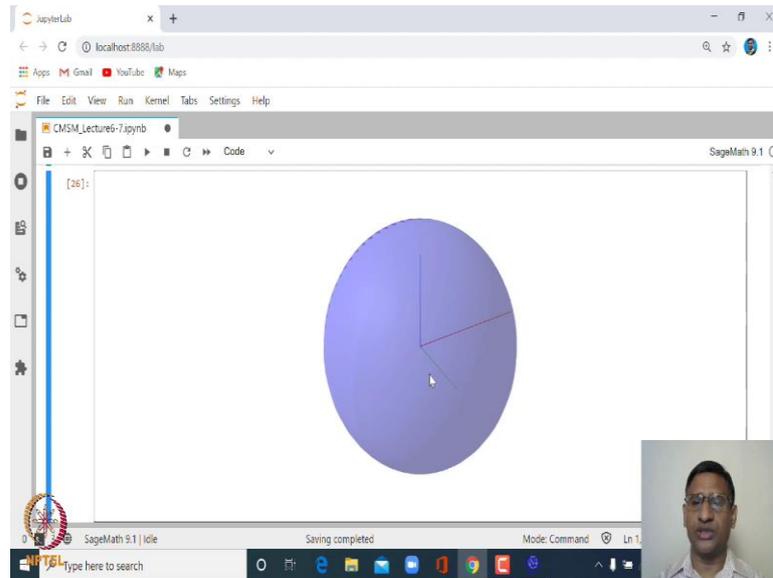

So, this is what you get. This is sphere and you can see the co-ordinate axis here. Now, we want to check what happens to this sphere when we apply A to it. When you multiply this sphere by A what happens. Multiplying A to this sphere is same as saying multiply first by V transpose then, multiply by S and then multiply by U.

(Refer Slide Time: 18:25)

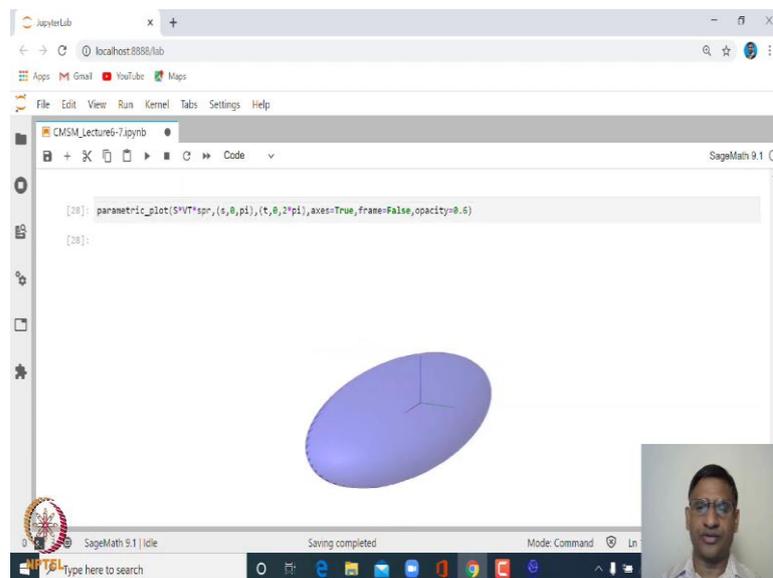

(Refer Slide Time: 18:29)

So, let us sequentially plot a graph of each of this. So, first let us plot graph of sphere multiplied by V transpose. V transpose times sphere. V transpose is actually orthogonal matrix. So, V transpose sphere will just be will get rotated. When you rotate a sphere, what you are going to get is a sphere itself. Of course, we can check what happens to unit vectors as we did in case of circle. That I will leave it as an exercise.

You can try to explore what happened to the unit vectors. Try to plot unit vectors e_1 , e_2 , e_3 along with the sphere and then add what happens to e_1 , e_2 , e_3 under V transpose.

(Refer Slide Time: 19:13)

Similarly, next let us apply S to it. V transpose sphere times S . Now, what you expect it to do? Let us just look at what is S ? S will be diagonal matrix.

(Refer Slide Time: 19:34)

```

[23]: ## Example
A=matrix(RDF, [[2,3,1],[-1,2,1],[0,2,3]])
U, S, VT = A.SVD()

[27]: S

[27]: [ 5.107364826956849  0.0  0.0]
      [ 0.0  2.292088864616885  0.0]
      [ 0.0  0.0  1.2779285813926738]

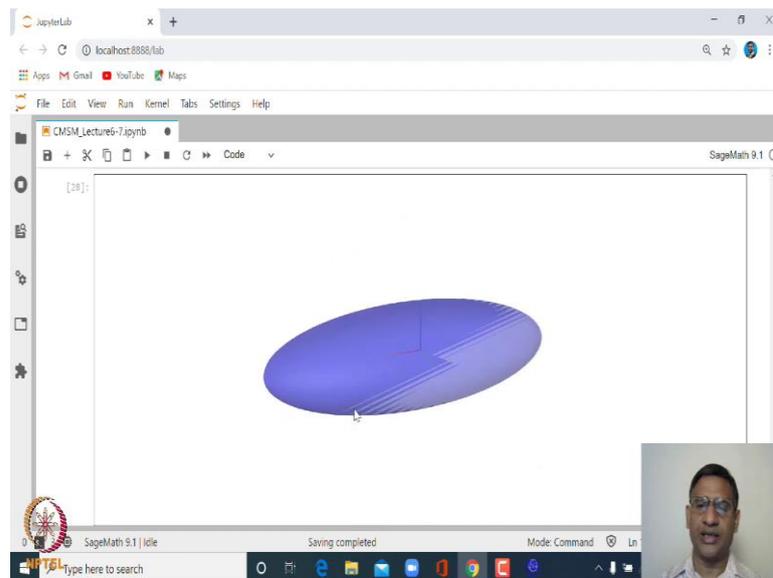

[24]: var('s,t')
spr=vector([sin(s)*cos(t), sin(s)*sin(t), cos(s)])

[25]: sphere=parametric_plot((sin(s)*cos(t), sin(s)*sin(t), cos(s)), (s,0,pi), (t,0,2*pi),
                           axes=True, frame=False, opacity=0.6)
sphere

[26]:
  
```

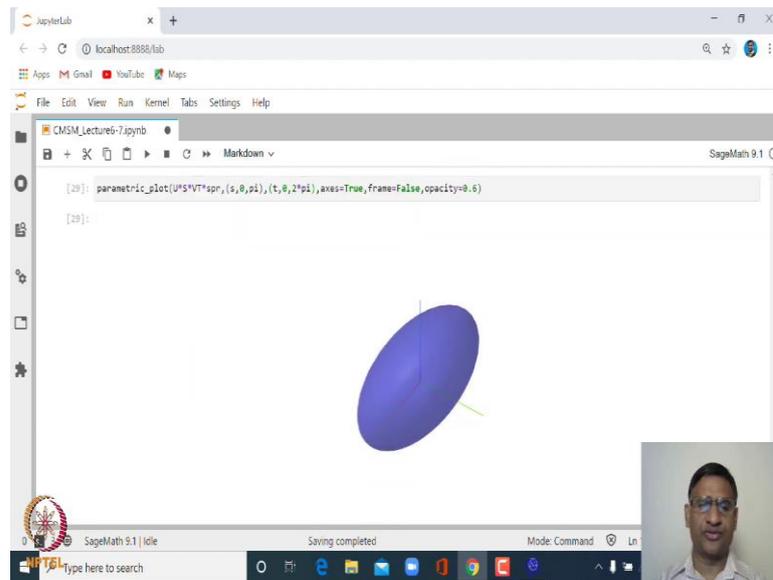

The first axis will get multiplied by 5.107. Second one will by about 2.292 and third one about by 1.0277. So, you this sphere now, will become an ellipsoid. Let us see that. Yes, that is what has happened. So, the sphere has become ellipsoid.

(Refer Slide Time: 20:08)

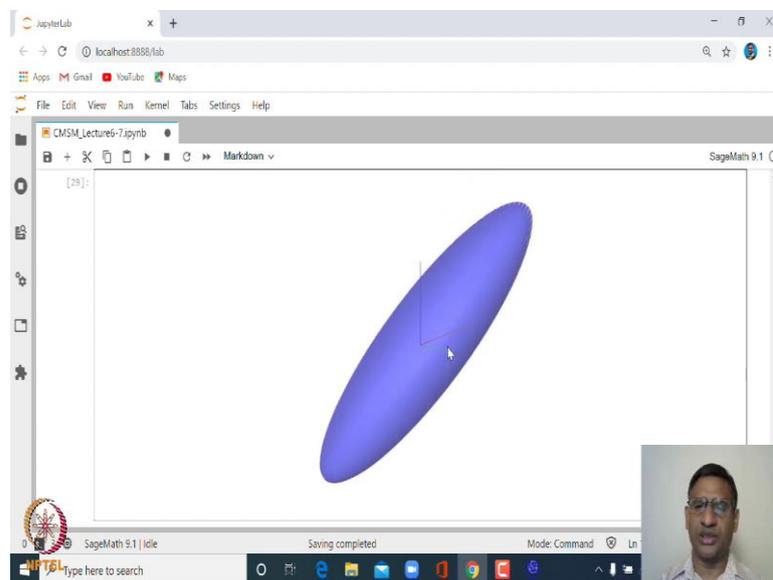

And you can see what happens to this unit vectors along the co-ordinate axis.

(Refer Slide Time: 20:15)

Then apply U to it. So, U times S times V transpose. So, this ellipsoid will get actually rotated by this U , because U is an orthogonal matrix. That is what you can see here.

(Refer Slide Time: 20:33)

Again it just gets rotated right. There is no change in the coordinates axis, but it only gets rotated. That is how you can explain geometric meaning of singular value decomposition, the multiplication of any matrix to any object in R^2 and R^3 right.

(Refer Slide Time: 21:08)

Pseudoinverse (Generalized Inverse)

Suppose $A = U \Sigma V^T$, then where

$$A^\dagger = V \Sigma^\dagger U^T.$$

$$\Sigma^\dagger = \begin{bmatrix} 1/\sigma_1 & 0 & \dots & 0 & 0 & \dots & 0 \\ 0 & 1/\sigma_2 & \dots & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots & 0 & 0 & \vdots \\ 0 & 0 & \dots & 1/\sigma_r & 0 & \dots & 0 \\ \hline 0 & 0 & \dots & 0 & 0 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \dots & 0 & 0 & \dots & 0 \end{bmatrix}_{m \times n}$$

Next let us look at how we can obtain generalized inverse using singular value decomposition. We have we have split A as U into sigma into V transpose. A is m cross n matrix and A is U into sigma into V transpose. You look at what is the property of the inverse of multiplication of two matrices. Inverse of A into B is nothing but B inverse into A inverse.

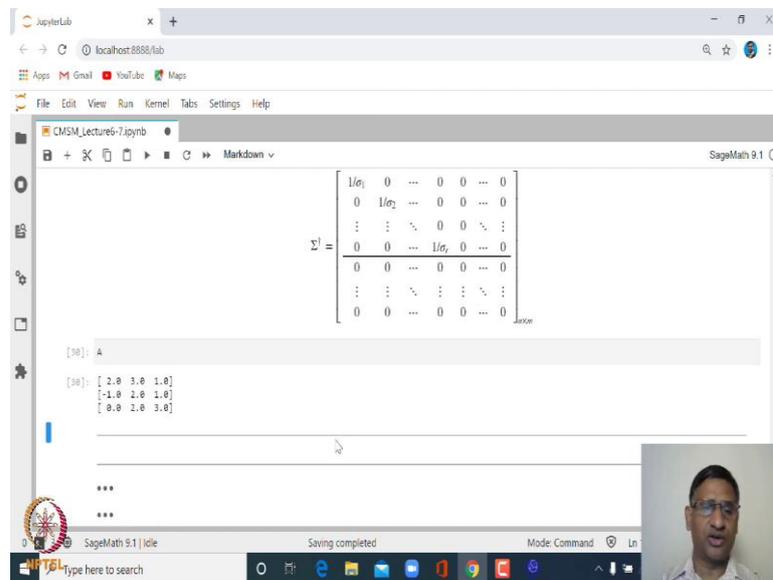

So, if I take inverse of this multiplication, this is going to inverse of A. Suppose, if it exists inverse of A is going to be inverse of U into sigma into V transpose, which is nothing but inverse of V transpose that is same as V into inverse of sigma and that and then, multiplied by inverse of U, which is U transpose.

But A may not be invertible, U and V are orthogonal matrices, they are invertible. Sigma is not a square matrix, this is a rectangular matrix. So, you have to define what is inverse of this kind of rectangular matrix, what is generalized inverse of this kind of rectangular matrix.

Now, let us just imagine, in case, Sigma happens to be square a diagonal matrix and if diagonal entries are all invertible, its inverse is nothing but the diagonal entries become one upon the diagonal entries of each of these. In case, diagonal entries are zero then, you cannot divide 1 by the diagonal entries. Then the generalised inverse of this sigma is going to be nothing but you just take a transpose of this matrix sigma and wherever you have diagonal entries which is non-zero, you take reciprocal. That is going to be

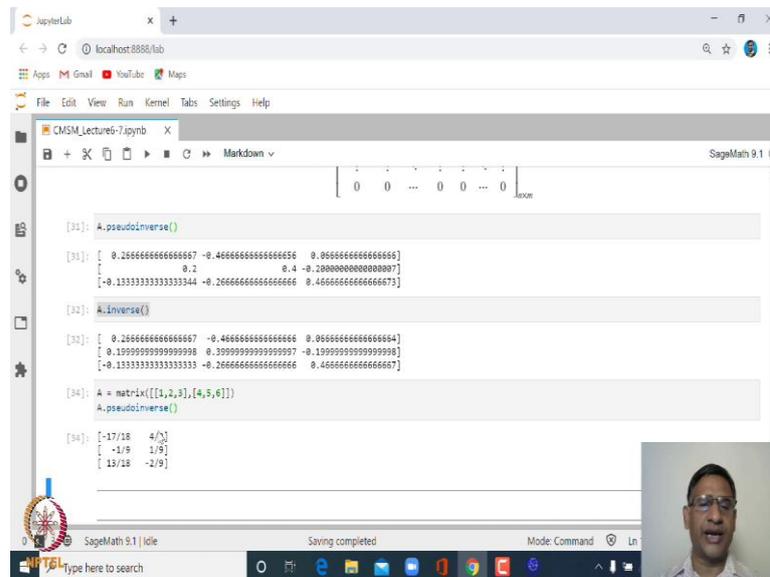

generalized inverse of sigma. So, this is quite easy to check. The generalized inverse of A, we denote it write it as A dagger is going to be V into generalized inverse of sigma into U transpose. So, that is very easy do this computation. Once we know singular value decomposition, this is very easy to compute. In this case all only the concept which is needed was the finding generalized inverse sigma which is a kind of diagonal matrix. So, this is how you can obtain. But of course, sage has inbuilt function to find the generalized inverse.

(Refer Slide Time: 23:50)

For example, take any matrix A. In this case A is a 3 cross 3 matrix.

Let us let us define A dot, it is called I think pseudoinverse. So, this is a generalized inverse. Now, if you look at what is A inverse? I this case A dot inverse if it exists. So, both are same.

In case A is invertible pseudo-inverse or generalized inverse will be same as its inverse. You can see here, they differ in decimal. The algorithm to compute pseudo-inverse may be different from the algorithm to compute inverse.

For example, let us take A to be a matrix, let us say, 1 2 3 and second row is let us say, 4 5 6 and we can find its generalized inverse. A dot pseudo-inverse, this is what you get pseudo-inverse of this.

You can try to verify the properties of this pseudo-inverse. For example, compute what happens to A into pseudo-inverse of A, The pseudo-inverse of A into A. All these properties you can you can verify. As I said earlier, using pseudo-inverse, you can also obtain least square solutions.

(Refer Slide Time: 25:31)

Practice Exercises

1. Find the SVD of a matrix $\begin{pmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 1 & -1 \end{pmatrix}$.
2. Find the least square solution of the system of equations $Ax = b$ where $A = \begin{pmatrix} 2 & 3 & -1 \\ -2 & 1 & 4 \\ 3 & 1 & 3 \\ -5 & 4 & 2 \\ 1 & 1 & 1 \end{pmatrix}$ and $b = \begin{pmatrix} -10 \\ 7 \\ 15 \\ 9 \end{pmatrix}$ using generalized inverse.

Let me leave few exercises for you. First is to find singular value decomposition of this matrix. Quite simple!

The second one is find least squares solution of Ax equal to b , where A is this.

(Refer Slide Time: 25:46)

Practice Exercises

1. Find the SVD of a matrix $\begin{pmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 1 & -1 \end{pmatrix}$.
2. Find the least square solution of the system of equations $Ax = b$ where $A = \begin{pmatrix} 2 & 3 & -1 \\ -2 & 1 & 4 \\ 3 & 1 & 3 \\ -5 & 4 & 2 \\ 1 & 1 & 1 \end{pmatrix}$ and $b = \begin{pmatrix} -10 \\ 7 \\ 15 \\ 9 \end{pmatrix}$ using generalized inverse.

And b is this, using pseudo-inverse or using generalized inverse.

(Refer Slide Time: 25:50)

Practice Exercises

- Find the SVD of a matrix $\begin{pmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 1 & -1 \end{pmatrix}$.
- Find the least square solution of the system of equations $Ax = b$ where $A = \begin{pmatrix} 2 & 3 & -1 \\ -2 & 1 & 4 \\ 3 & 1 & 3 \\ -1 & 4 & 2 \\ 1 & 1 & 1 \end{pmatrix}$ and $b = \begin{pmatrix} -10 \\ 7 \\ 15 \\ 8 \\ 9 \end{pmatrix}$ using generalized inverse.

The least squares solution, x^* is going to be a pseudo-inverse of A times b . So, you simply compute pseudo-inverse of this, which is we denote by A^\dagger . So, A^\dagger times b is what you need to compute. It is a very easy exercise. Now, let me leave one more exercise.

(Refer Slide Time: 26:19)

Practice Exercises

- Find the SVD of a matrix $\begin{pmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 1 & -1 \end{pmatrix}$.
- Find the least square solution of the system of equations $Ax = b$ where $A = \begin{pmatrix} 2 & 3 & -1 \\ -2 & 1 & 4 \\ 3 & 1 & 3 \\ -1 & 4 & 2 \\ 1 & 1 & 1 \end{pmatrix}$ and $b = \begin{pmatrix} -10 \\ 7 \\ 15 \\ 8 \\ 9 \end{pmatrix}$ using generalized inverse.

* Find the generalized inverse of $A = \begin{pmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 1 & -1 \end{pmatrix}$

Find the generalized inverse of let us say A, which is, let me just copy this here, A is equal to this 3 cross 2 matrix. Earlier rows what was the one which we took was 2 cross 3 matrices. So, in this case now, what you may have to do find the generalized inverse.

The screenshot shows a JupyterLab window with a SageMath 9.1.0 notebook. The notebook content is as follows:

Practice Exercises

1. Find the SVD of a matrix $\begin{pmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 1 & -1 \end{pmatrix}$.
2. Find the least square solution of the system of equations $Ax = b$ where $A = \begin{pmatrix} 2 & 3 & -1 \\ -2 & 1 & 4 \\ 3 & 1 & 3 \\ -5 & 4 & 2 \\ 1 & 1 & 1 \end{pmatrix}$ and $b = \begin{pmatrix} -10 \\ 7 \\ 15 \\ 8 \\ 9 \end{pmatrix}$ using generalized inverse.

- Find the generalized inverse of $A = \begin{pmatrix} 1 & 1 \\ 2 & 2 \\ 3 & 1 \end{pmatrix}$

(Refer Slide Time: 27:28)

The screenshot shows the same JupyterLab window, but the notebook content is rendered in a code-like font for better readability:

Practice Exercises

1. Find the SVD of a matrix $\begin{pmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 1 & -1 \end{pmatrix}$.
2. Find the least square solution of the system of equations $Ax=b$ where $A = \begin{pmatrix} 2 & 3 & -1 \\ -2 & 1 & 4 \\ 3 & 1 & 3 \\ -5 & 4 & 2 \\ 1 & 1 & 1 \end{pmatrix}$ and $b = \begin{pmatrix} -10 \\ 7 \\ 15 \\ 8 \\ 9 \end{pmatrix}$ using generalized inverse.

- Find the SVD of $A = \begin{pmatrix} 1 & 1 \\ 2 & 2 \\ 3 & 1 \end{pmatrix}$

(Refer Slide Time: 27:32)

The screenshot shows a SageMath 9.1 interface with the following content:

Practice Exercises

1. Find the SVD of a matrix $\begin{pmatrix} 1 & 1 & 1 \\ 2 & 2 & 2 \\ 3 & 1 & -1 \end{pmatrix}$.

2. Find the least square solution of the system of equations $Ax = b$ where $A = \begin{pmatrix} 2 & 3 & -1 \\ -2 & 1 & 4 \\ 3 & 1 & 3 \\ -5 & 4 & 2 \\ 1 & 1 & 1 \end{pmatrix}$ and $b = \begin{pmatrix} -10 \\ 7 \\ 15 \\ 8 \\ 9 \end{pmatrix}$ using generalized inverse.

• Find the SVD of $A = \begin{pmatrix} 1 & 1 \\ 2 & 2 \\ 3 & 1 \end{pmatrix}$

The interface also shows a video feed of a person in the bottom right corner and a status bar at the bottom indicating 'Saving completed' and 'Mode: Command'.

I will say SVD of this matrix. So, in this case what you may have to do. When you look at this $A^T A$, $A A^T$ in this case is going to be a 3 by 3 matrix whereas, $A^T A$ will be 2 cross 2 matrix. So, you need to define two vectors v_1 and v_2 for a capital V and then, three vectors u_1, u_2, u_3 for U .

Now, the question is how we obtain; u_1 and u_2 , you can obtain from v_1 and v_2 , but for u_3 you may have to take a vector which is orthogonal to u_1 and u_2 ; that is what it means. That is why I gave you this exercise.

We will look at some more applications in the next class. So, let me stop here.

Thank you very much.
