Monotone Convergence Theorem for Upper Functions

(Refer Slide Time: 00:22)

Levi Monotone conv. thm for upper fns.

Theorem: let $f_n: I \rightarrow \mathbb{R}$ be a seq. of upper fn. s.t.

(i). f_n increases a.e. on I .

(ii). $\lim_{h \rightarrow \infty} \int_I f_n$ exists.

Then f_n conv. a.e. to a fn $f \in U(I)$ and

$$\int_I f = \lim_{h \rightarrow \infty} \int_I f_n.$$

In this week we are going to see a proof of Levis Monotone Convergence Theorem for Upper Functions. We have already proved the theorem for step functions, in this video we will adapt the argument given there to the general case of upper functions. In the next video we will break up a Labesgue integrable function as a difference of two upper functions and get a Levi monotone convergence theorem for all Labesgue integrable functions.

So, here is the statement of the theorem its exactly similar to what we have seen for step functions. Let F_n from I to \mathbb{R} be a sequence of upper functions, such that number 1, F_n increases almost everywhere on I .

Note there is a slight difference in this version compared to what we saw in the last video, there we assume that the step functions are increasing everywhere. But simply because step functions take only finitely many values, think about why assuming almost everywhere for step functions makes no sense.

Second; limit n going to infinity integral over I F_n exists. So, the integrals are bounded above in a sense, then F_n converges almost everywhere to a function F which is an upper function and the integral of F is nothing but the limit of n going to infinity integral of I F_n . So, in some sense you can interchange the limit and the integral the limit and the integral can be interchanged.

One nice aspect about the monotone convergence theorem is that we are just assuming that the limit n going to infinity integral of I F_n exists that automatically guarantees the existence of a limit function F whose integral is exactly the limit of the integrals which is something nice ok. So, as I said we are going to use the fact that we have already shown for step functions.

(Refer Slide Time: 02:47)

NPTEL

Proof: By defn., we can find an increasing
 seq. of step fns.
 $S_{n,k}$ that generate F_k .
 $S_{n,k} \rightarrow F_k$ (n is the index)
 a.e.

$\lim_{n \rightarrow \infty} \int_I S_{n,k}$ exists.

$S_{1,1} \quad S_{1,2}, \quad S_{1,3}, \dots, \quad F_1$
 $S_{1,2} \quad S_2$

So, proof by definition we can find, we can find an increasing sequence an increasing sequence of step functions $S_{n,k}$ that generate F_k . Recall this means that $S_{n,k}$ increases almost everywhere to F_k here n is the index n is the index. So, I should write almost everywhere and this integral $S_{n,k}$ over I this limit n going to infinity exists this is the meaning of $S_{n,k}$ s generate F_k .

So, let us arrange them all in an array we have $S_{1,1}, S_{1,2}, S_{1,3}, \dots$ and this increases almost everywhere to F_1 . Similarly, we have the second one $S_{1,2}, S_I$ made a slight mistake in the indexing the running index is n not k , so let me just fix that.

(Refer Slide Time: 04:13)

NPTEL

Proof: By defn., we can find an increasing seq. of step fns. $S_{n,k}$ that generate F_k . $S_{n,k} \rightarrow F_k$ a.e. (n is the index)

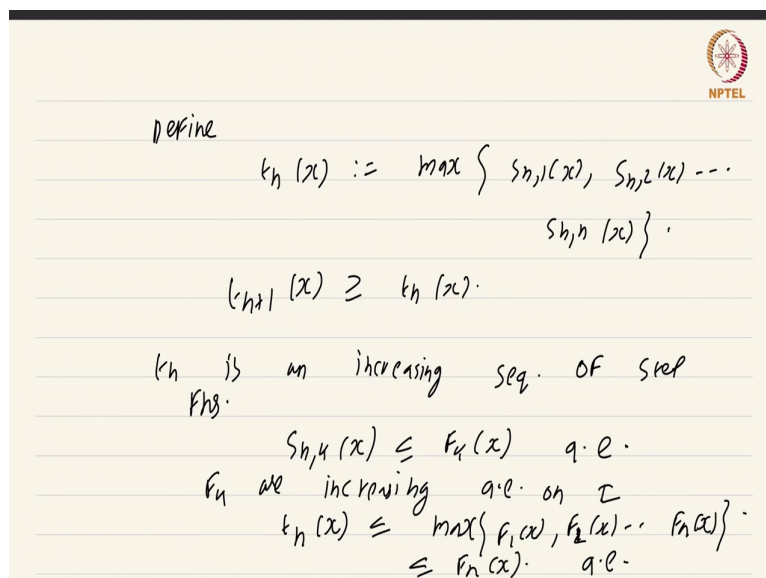

$\lim_{h \rightarrow \infty} \int_I S_{n,k}$ exists.

$S_{1,1}$	$S_{2,1}$	\longrightarrow	F_1
$S_{1,2}$	$S_{2,2}$	\longrightarrow	F_2
\vdots	\vdots	\dots	\dots

So, you have $S_{1,1}$ you have $S_{2,1}$ dot dot dot converging to F_1 , then you have $S_{1,2}$ $S_{2,2}$ dot dot dot converging to F_2 , you have this in both directions ok. And note these $S_{n,k}$ s are increasing sequence of step functions they are an increasing sequence of step functions and they increase almost everywhere to F_k ok.

Now, what we are going to do is we are going to produce new step functions combining together the data obtained by these step functions which converge to F_k right.

(Refer Slide Time: 05:02)

define

$$t_n(x) := \max \{ s_{n,1}(x), s_{n,2}(x) \dots s_{n,n}(x) \}.$$
$$t_{n+1}(x) \geq t_n(x).$$

t_n is an increasing seq. of step fns.

$$s_{n,k}(x) \leq f_k(x) \quad \text{q.e.}$$

f_n are increasing q.e. on \mathbb{I}

$$t_n(x) \leq \max \{ f_1(x), f_2(x) \dots f_n(x) \} \leq f_n(x) \quad \text{q.e.}$$

So, what we do is, we define t_n of x by definition to be max of $S_{n,1}$ of x , $S_{n,2}$ of x comma dot dot dot $S_{n,n}$ of x right. So, what are we doing? We are looking at the n th column we are looking at the n th column and we are taking the max all the way up till the n th entry ok. So, we start at for instance t_{11} would be just $S_{1,1}$ sorry t_1 would be just $S_{1,1}$ t_2 would be the maximum of $S_{2,1}$ and $S_{2,2}$ ok and t_3 will be the maximum of $S_{3,1}$, $S_{3,2}$, $S_{3,3}$ all the way up till the third entry ok.

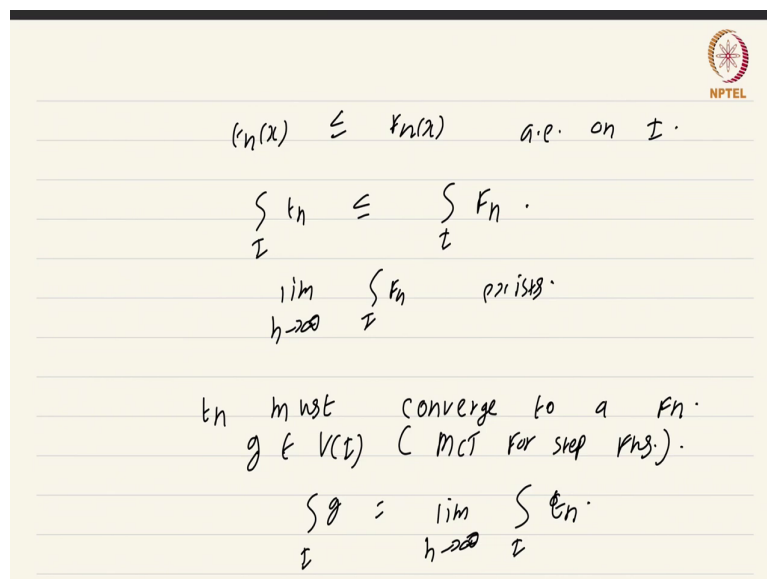

Now, because we are taking the maximum always to the right that is t_{n+1} will be obtained by taking a maximum of functions which are to the right of the functions that you are taking for t_n . And since each row the functions are increasing its straightforward to see that t_{n+1} of x is greater than or equal to t_n of x , that is t_n is an increasing sequence.

Furthermore, since it is a maximum of finitely many step functions it is also a step function it is an increasing sequence of step functions excellent.

Now, by definition we have $S_n(x)$ is less than or equal to $F(x)$ almost everywhere, because this is because the sequence S_n generate the function F . And since F is increasing almost everywhere on I we automatically have that $S_n(x)$ is going to be less than the maximum of $F_1(x), F_2(x), \dots, F_n(x)$.

Now of course, this will be true almost everywhere this will be true almost everywhere and notice that because these functions F_1, F_2, \dots, F_n are also increasing almost everywhere I can write this is less than or equal to $F_n(x)$ almost everywhere.

(Refer Slide Time: 07:59)

$$f_n(x) \leq F_n(x) \quad \text{a.e. on } I.$$

$$\int_I f_n \leq \int_I F_n.$$

$$\lim_{n \rightarrow \infty} \int_I f_n \text{ exists.}$$

$$f_n \text{ must converge to a } F_n.$$

$$g \in V(I) \text{ (MCT for step fns.)}$$

$$\int_I g = \lim_{n \rightarrow \infty} \int_I f_n.$$

So, the net upshot is t_n of x is less than or equal to F_n of x almost everywhere on I ok. Now both sides are upper functions, so we can use the results involving upper functions and the behaviour of integrals under order to conclude that $\int_I t_n$ is less than or equal to $\int_I F_n$.

But our hypothesis is that $\lim_{n \rightarrow \infty} \int_I F_n$ exists and since this sequence of integrals is an increasing sequence, this means this quantity $\int_I F_n$ is bounded above. Which means that $\int_I t_n$ is bounded above and since these t_n s are increasing functions the net conclusion is that t_n s must converge to a function g in U of I and this follows from monotone convergence theorem for step functions ok.

So, we have just constructed these new step functions which are increasing and because these new step functions are increasing and they are bounded above we get that we get a limit function and not only that we get that $\int_I g = \lim_{n \rightarrow \infty} \int_I t_n$ ok.

(Refer Slide Time: 09:52)

Goal: $F_n \rightarrow F$ a.e. and $\int F = \lim_{n \rightarrow \infty} \int F_n$.

$S_{h,h}(x) \le t_n(x)$ if $k \le h$.

$F_n(x) \le F(x)$ a.e.

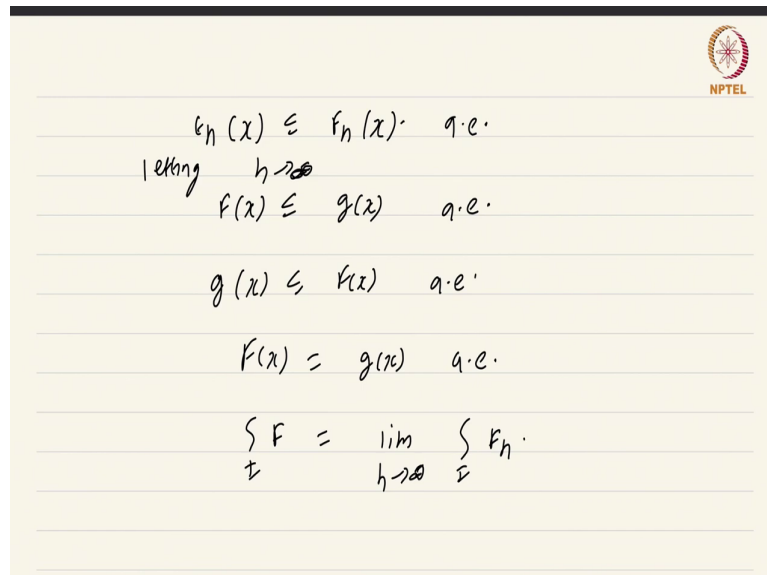

The increasing seq. (a.e.) F_n is a.e. bdd. above by F . This means F_n is a.e. bounded above by F .

Now, what do we do now? We are going to show, goal is to show that F_n converges to F almost everywhere and integral of F is nothing but limit of n going to infinity integral of F_n . Let us keep this goal in mind. Now, as we have observed before $S_{n,k}(x)$ is less than or equal to $t_k(x)$ if $k \leq n$. This is because we are just taking the maximum of $S_{n,1}, S_{n,2}, \dots, S_{n,n}$, so this is just by definition.

Now, take n going to infinity. So, what you will get is $F_k(x)$ is less than or equal to $\lim_{n \rightarrow \infty} t_n(x)$ which is just $F(x)$. But this will be true only almost everywhere. This means that the increasing sequence that is it is almost everywhere increasing of course, F_k is almost everywhere bounded above by F .

This means F_k converges almost everywhere to some function g from I to \mathbb{R} . But we already know that by our construction these functions $t_n(x)$ are less than or equal to $F_n(x)$.

(Refer Slide Time: 11:45)

The slide contains the following handwritten mathematical steps:

$$t_n(x) \leq F_n(x) \quad \text{a.e.}$$

letting $n \rightarrow \infty$

$$f(x) \leq g(x) \quad \text{a.e.}$$

$$g(x) \leq f(x) \quad \text{a.e.}$$

$$f(x) = g(x) \quad \text{a.e.}$$

$$\int_I f = \lim_{n \rightarrow \infty} \int_I F_n.$$

Recall, these $t_n(x)$ s were obtained by taking the maximum along the n th column all the way up till the n . And since the functions here to the right are all almost everywhere greater than or equal to we get this inequality that $t_n(x)$ is less than or equal to $F_n(x)$ almost everywhere ok.

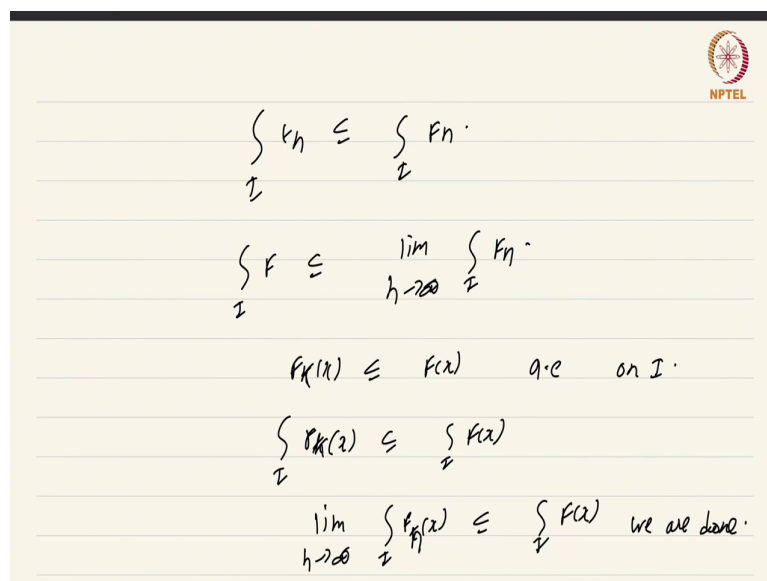

Now letting n go to infinity letting n go to infinity we get that the limit of the left hand side is $f(x)$ by definition and the limit of the right hand side is $g(x)$ and this is true almost

everywhere ok. But we also have we also have g of x is less than or equal to F of x almost everywhere.

Why do we have g of x is less than or equal to F of x almost everywhere? Well, we already know that F_k of x is less than or equal to F of x and this is just the point wise limit of F_k of x , therefore g of x will be less than or equal to F of x combining both we get F of x equal to g of x almost everywhere excellent.

Now, we have to show what remains to be shown is integral of $I F$ is limit n going to infinity integral of $I F_n$ ok.

(Refer Slide Time: 13:30)

$$\int_I f_n \leq \int_I F_n$$

$$\int_I F \leq \lim_{n \rightarrow \infty} \int_I F_n$$

$$f(x) \leq F(x) \quad \text{q.e. on } I$$

$$\int_I f(x) \leq \int_I F(x)$$

$$\lim_{n \rightarrow \infty} \int_I f_n(x) \leq \int_I F(x) \quad \text{we are done.}$$

We have the following relationship that we have obtained earlier integral of $I f_n$ is less than or equal to integral of $I F$ and taking limits will tell you that integral of $I F$ is less than or

equal to $\lim_{n \rightarrow \infty} \int I F_n$. We also have the relationship that F_k of x is also less than or equal to F of x almost everywhere on I .

And again that means, that $\int I F_k$ of x is less than or equal to $\int I F$ of x and taking limits on both sides tells you that $\lim_{n \rightarrow \infty} \int I F_n$ of x or rather $\lim_{n \rightarrow \infty} \int I F_n$ of x is less than or equal to $\int I F$ of x and we are done we are done.

So, this concludes the proof of Levis monotone convergence theorem for upper functions, in the next video we shall use this result to show the similar result for Lebesgue integrable functions. This is a course on Real Analysis and you have just watched the video on Levi monotone convergence theorem for upper functions.
