Lecture 15
Construction of Green's Function-2

Hello friends here we will continue in this lecture we are going to continue the previous talk that is on Green function.

(Refer Slide Time: 0:36)

So in previous lecture we have discussed this particular problem $u'' = \phi(x)$ where x is between 0 to 1 and $u(0) = 0$ and $u(1) = 0$. So we try to find out the solution $u(x)$ in this integral form $G(\xi, x) \phi(\xi) d\xi$ and where $G(\xi, x)$ is defined earlier. Now we try to look at the more complicated example here if you look at we simply solved our Green function by saying that G will satisfy this equation that $L^* G$ which is nothing but $G_{\xi\xi}(\xi, x) = \delta(\xi - x)$ and $G(1, x) = 0 = G(0, x)$.

So here we have find this $G(\xi, x)$ we simply integrated it and we have achieved $G(\xi, x)$ as $(\xi - x)H(\xi - x) + x - 1$. So here this is quite easy because our operator is quite easy we simply integrated. Now let us discuss a little bit little bit more complicated problem where this integration is not so straight.

(Refer Slide Time: 2:22)

Example 2

Consider the problem

$$u'' + 3u' + 2u = \phi; \quad u(1) = 2u(0), \quad u'(1) = a \quad (18)$$

where a is a real constant. We may observe that in this example

- L is not formally self adjoint,
- the first boundary condition is mixed.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

So let us consider the second problem here we have seen $u'' + 3u' + 2u = \phi$, where $u(1) = 2u(0)$ and $u'(1) = a$. So in previous problem we have considered the boundary condition which are homogeneous boundary condition but here we have considered a non-homogeneous condition and the first boundary condition is a mixed boundary condition that it involves both $u(0)$ and $u'(0)$. And if you look at here this L is not given as formally a self adjoint, if you look at your a is simply 1 and B is 3 and B is not given as A' . So it is not a self adjoint equation.

(Refer Slide Time: 3:10)

As we have done in previous example,

$$\begin{aligned} \int_0^1 GLu d\xi &= \int_0^1 G(u'' + 3u' + 2u) d\xi \\ &= (Gu' - G_\xi u + 3Gu)|_0^1 + \int_0^1 u(G_{\xi\xi} - 3G_\xi + 2G) d\xi \\ &= u(0)[6G(1, x) - 3G(0, x) - 2G_\xi(1, x) + G_\xi(0, x)] \\ &\quad + aG(1, x) - G(0, x)u'(0) + \int_0^1 uL^*G d\xi \end{aligned} \quad (19)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

Example 2

Consider the problem

$$u'' + 3u' + 2u = \phi; \quad u(1) = 2u(0), \quad u'(1) = a \quad (18)$$

where a is a real constant. We may observe that in this example

- L is not formally self adjoint,
- the first boundary condition is mixed.

So to solve this we adopt the same method and what we try to do is we define L as $L u = u'' + 3u' + 2u$. So we multiply by Green function G and integrate between 0 to 1. So if you do the same thing we have $\int_0^1 G u'' + 3u' + 2u \, dx$ and as we did in previous lecture we transfer the derivative of u and u' on this G and this is the process integrated here and at the end we are going to get this.

Here I have utilized this condition that $u(1) = 2u(0)$ not, if you utilize the condition it is simplified as $u(1) = 2u(0)$ within bracket $6G(1,x) - 3G(0,x) - 2G_x(1,x) + G_x(0,x) + aG(1,x) - G(0,x)u'(0) + \int_0^1 u L^* G \, dx$. Now if you follow the if you want to get our solution then here we simply say that $L^* G$ is going to be $\delta(x - \xi)$ and we define $G(0,x) = 0$.

(Refer Slide Time: 4:30)

Handwritten mathematical derivation on a whiteboard:

$$\int_0^1 G L u \, dx = u(0) \left[6G(1,x) - 3G(0,x) - 2G_x(1,x) + G_x(0,x) \right] + a G(1,x) - G(0,x)u'(0) + \int_0^1 u L^* G \, dx$$

$$\int_0^1 G \cdot \phi \, dx = \alpha G(1,x) + u(x)$$

$$\Rightarrow u(x) = -\alpha G(1,x) + \int_0^1 G \cdot \phi \, dx$$

Boundary conditions and adjoint operator:

$$L^* G = \delta(\xi - x)$$

$$G(0,x) = 0$$

$$6G(1,x) - 2G_x(1,x) + G_x(0,x) = 0$$

So here we have write this $0 \leq \xi \leq 1$ $G_{\xi\xi} - 3G_{\xi} + 2G = \delta(\xi - x)$ is equal to $u(0)$ within bracket we have $6G(1, x) - 3G(0, x) - 2G_{\xi}(1, x) + G_{\xi}(0, x)$ plus $G(1, x) - G(0, x)$ dash 0 plus $0 \leq \xi \leq 1$ $uL^*G d\xi$. So here to get our solution we assume that (u) this L^*G is going to be $\delta(\xi - x)$ and the condition on this G boundary condition is $G(0, x) = 0$ so that this term is simply vanished and we assume that this condition since $u(0)$ is not given so we assume that $6G(1, x) - 3G(0, x) - 2G_{\xi}(1, x) + G_{\xi}(0, x)$ is equal to 0 .

So we try to find out our Green function which satisfy this condition that L^*G is equal to $\delta(\xi - x)$ and $G(0, x) = 0$ and this is equal to 0 . So if we assume this this term is gone, this term is gone. And you can write it here $0 \leq \xi \leq 1$ $G_{\xi\xi} - 3G_{\xi} + 2G = \delta(\xi - x)$ is given as $\phi d\xi$ is equal to $aG(1, x) + 0 \leq \xi \leq 1$ uL^*G . But if you take L^*G as $\delta(\xi - x)$ then this is going to be $u(x)$, so your $u(x)$ is given as $-aG(1, x) + 0 \leq \xi \leq 1$ $G_{\xi\xi} - 3G_{\xi} + 2G = \delta(\xi - x)$. So we need to calculate this G .

(Refer Slide Time: 7:10)

If Green's function satisfies

$$L^*G = G_{\xi\xi} - 3G_{\xi} + 2G = \delta(\xi - x) \quad (20)$$

together with boundary conditions

$$G(0, x) = 0 \quad (21)$$

$$6G(1, x) - 2G_{\xi}(1, x) + G_{\xi}(0, x) = 0 \quad (22)$$

then the solution from (19), with Lu replaced by ϕ will be given by

$$u(x) = -aG(1, x) + \int_0^1 G(\xi, x)\phi(\xi)d\xi \quad (23)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

As we have done in previous example,

$$\begin{aligned}
 \int_0^1 GLud\xi &= \int_0^1 G(u'' + 3u' + 2u)d\xi \\
 &= (Gu' - G_\xi u + 3Gu)|_0^1 + \int_0^1 u(G_{\xi\xi} - 3G_\xi + 2G)d\xi \\
 &= u(0)[6G(1, x) - 3G(0, x) - 2G_\xi(1, x) + G_\xi(0, x)] \\
 &\quad + aG(1, x) - G(0, x)u'(0) + \int_0^1 uL^*Gd\xi \quad (19)
 \end{aligned}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

So we have seen that if our Green function satisfy this property that L^*G which is defined as $G_{\xi\xi} - 3G_\xi + 2G = \delta(\xi - x)$ along with the condition $G(0, x) = 0$ and $6G(1, x) - 2G_\xi(1, x) + G_\xi(0, x) = 0$ then the previous this is going to be u of x and it is equal to minus of $aG(1, x) + 0$ to $1 GLud\xi$ which is given as u of x equal to minus $aG(1, x) + 0$ to $1 GLud\xi$.

But if you look at here this G which is solution of this differential equation is not easy to solve because it is not done by direct integration.

(Refer Slide Time: 7:58)

Here $\delta(\xi - x) = 0$ for all $\xi \neq x$, it will be convenient to split the interval into two parts, $0 \leq \xi < x$ and $x < \xi \leq 1$ (in each of which $L^*G = 0$).
Now G is given by

$$G(\xi, x) = \begin{cases} Ae^\xi + Be^{2\xi}, & 0 \leq \xi < x; \\ Ce^\xi + De^{2\xi}, & x \leq \xi < 1. \end{cases} \quad (24)$$

To determine the coefficients A, B, C and D we have the two boundary conditions by which we get

$$A + B = 0 \quad (25)$$

$$A + 2B + 4eC + 2e^2D = 0. \quad (26)$$

plus two matching conditions, which blend the two parts of (24) suitably at $\xi = x$.
For utilizing the matching conditions, we integrate equation (20) from $x - 0$ to $x + 0$,

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

If Green's function satisfies

$$L^*G = G_{\xi\xi} - 3G_{\xi} + 2G = \delta(\xi - x) \quad (20)$$

together with boundary conditions

$$G(0, x) = 0 \quad (21)$$

$$6G(1, x) - 2G_{\xi}(1, x) + G_{\xi}(0, x) = 0 \quad (22)$$

then the solution from (19), with Lu replaced by ϕ will be given by

$$u(x) = -aG(1, x) + \int_0^1 G(\xi, x)\phi(\xi)d\xi \quad (23)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

So here we use the property of Dirac delta function that delta xi minus x is 0 for all xi not equal to x. So what we try to do is we split our interval into two part, one is between 0 and x and between x to 1. So in each interval your delta xi minus x is equal to 0, so we can say that G is going to be a solution of this homogeneous equation L star G equal to 0.

So it means that we can get the solution we can get the expression of G by solving L star G equal to 0 and if you look at your G star is a simple order linear order differential equation with constant coefficient. So we can easily find out the solution and it can be written as that the general solution of this problem is given as constant times of e to power xi plus constant times of e to power 2 xi.

So we can write G as G xi, x as Ae to power xi plus Be to power 2 xi between 0 to x and between x to 1 it is another constant Ce to power xi plus De to power 2 xi. Now we can find out these constant A, B, C and D with the help of boundary condition we have assumed. So boundary condition is what boundary condition we have assumed that G of 0, x equal to 0 and this is the boundary condition.

So we if we apply these two boundary condition we can have this relation that A plus B equal to 0 and A plus 2B plus (4e to power) 4eC plus 2e square D equal to 0. Now along with this we have two matching condition also which is which we can obtain by the problem itself that L star G equal to delta xi minus x. So to get that matching condition what we try to do we simply integrate the L star G equal to delta xi minus x from x minus 0 to x plus 0.

(Refer Slide Time: 10:12)

$$\int_{x-0}^{x+0} (G_{\xi\xi} - 3G_{\xi} + 2G)d\xi = \int_{x-0}^{x+0} \delta(\xi - x)d\xi \quad (27)$$

$$G_{\xi}|_{x-0}^{x+0} - 3G|_{x-0}^{x+0} + 2 \int_{x-0}^{x+0} Gd\xi = 1 \quad (28)$$

If we have that $G(\xi, x)$ be a continuous function of ξ at $\xi = x$ then the second and third part of (28) drop out, exposing the jump condition on the slope

$$G_{\xi}|_{x-0}^{x+0} = 1 \quad (29)$$

Thus G is continuous at $\xi = x$. In terms of continuity of Green's function and (29)

$$A + Be^x - C - De^x = 0 \quad (30)$$

$$-Ae^x - 2Be^{2x} + Ce^x + 2De^{2x} = 1 \quad (31)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

Here $\delta(\xi - x) = 0$ for all $\xi \neq x$, it will be convenient to split the interval into two parts, $0 \leq \xi < x$ and $x < \xi \leq 1$ (in each of which $L^*G = 0$). Now G is given by

$$G(\xi, x) = \begin{cases} Ae^{\xi} + Be^{2\xi}, & 0 \leq \xi < x; \\ Ce^{\xi} + De^{2\xi}, & x \leq \xi < 1. \end{cases} \quad (24)$$

To determine the coefficients A, B, C and D we have the two boundary conditions by which we get

$$A + B = 0 \quad (25)$$

$$A + 2B + 4eC + 2e^2D = 0. \quad (26)$$

plus two matching conditions, which blend the two parts of (24) suitably at $\xi = x$. For utilizing the matching conditions, we integrate equation (20) from $x - 0$ to $x + 0$,

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

So which is nothing but (integration of x minus) integration of this term from x minus 0 to x plus 0. So here using the filtering property we have 1 here and this we can integrate. So I can have G_{ξ} evaluating at minus x minus 2 x plus and so on. Now here so far our G is completely arbitrary but to simplify our calculation what we can assume if we assume that G_{ξ} , x is a continuous function of ξ at ξ equal to x then this second term and the third term is going to vanish and we have one term left that is G_{ξ} from x minus to x plus is equal to 1. So here we simply say that this is a jump condition on the slope.

So here with this these assumptions we can say that our G is continuous at ξ equal to x , so we have this condition that A plus Be to power x minus C minus De to power x equal to 0, this is done by using the continuity of G at ξ equal to x and the jump condition at of G_{ξ}

from x minus to x plus we have this last condition minus Ae to power x minus $2Be$ to power $2x$ plus Ce to power x plus $2De$ to power $2x$ equal to $1x$.

So now we have four conditions this 25 and 26 that A plus B equal to 0 and A plus $2B$ plus $4eC$ plus $2e$ square D equal to 0 and two condition which we have obtained by assuming that G is continuous and G has jump discontinuity at the first order derivative.

(Refer Slide Time: 12:01)

On solving, we obtain

$$G(\xi, x) = \begin{cases} \frac{1}{k}(2e^{2-2x} - 4e^{1-x}(e^\xi - e^{2\xi})), & 0 \leq \xi \leq x; \\ \frac{1}{k}[(2e^{2-x} - 2e^2 - 1)e^{\xi-x} \\ + (4e - 4e^{1-x} + e^{-x})e^{2\xi-x}], & x \leq \xi \leq 1. \end{cases} \quad (32)$$

Note
In this case $G(\xi, x)$ is not symmetric since the differential operator is not self-adjoint.

IT ROORKEE
NPTL ONLINE
CERTIFICATION COURSE
15

So if you use all these condition we can find out A , B , C and D and we can write down our solution as $G(\xi, x)$ equal to this expression. Now here we may observe that this $G(\xi, x)$ is not symmetric. But this is quite clear because the initial operator L is not a self adjoint operator. So this symmetricity will come when we have L as self adjoint operator. So in case of self adjoint operator our Green function is coming out to be asymmetric Green function, okay.

(Refer Slide Time: 12:54)

Construction of Green's Function for Ordinary Differential Equations

Suppose we have a linear differential equation of order n :

$$L[y] \equiv p_0(x)y^n + p_1(x)y^{(n-1)} + \dots + p_n(x)y = 0, \quad (33)$$

where all the coefficients are continuous on $[a, b]$, $p_0(x) \neq 0$ on $[a, b]$, and the boundary conditions are

$$V_k(y) := \alpha_k y(a) + \alpha_k^1 y'(a) + \dots + \alpha_k^{n-1} y^{(n-1)}(a) + \beta_k y(b) + \beta_k^1 y'(b) + \dots + \beta_k^{n-1} y^{(n-1)}(b) = 0, \quad k = 1, 2, \dots, n. \quad (34)$$

where the linear forms V_1, \dots, V_n in $y(a), y'(a), \dots, y^{(n-1)}(a), y(b), \dots, y^{(n-1)}(b)$ are linearly independent.

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 16

So now let us generalize this concept of constructing the Green function to a general n th order linear differential equation. So for this let us consider n th order linear differential equation defined as $L y$ operating $L y$ defined as this $p_0(x)y^n + p_1(x)y^{n-1}$ and so on. Here we have assumed that all the coefficients $p_0(x), p_1(x), p_2(x)$ all are continuous on this close interval a, b and additionally we assume that $p_0(x)$ is nonzero in this interval a to b and boundary conditions are here we have assumed that these are mixed boundary condition this is general most boundary condition we have assumed.

So $V_k(y)$ is the boundary condition this is n boundary condition given k from 1 to n . So here this $\alpha_k y(a) + \alpha_k^1 y'(a)$ and so on these are the boundary condition defined at the starting point that is a and $\beta_k y(b) + \beta_k^1 y'(b)$ and $\beta_k^{n-1} y^{(n-1)}(b)$ these are the boundary condition given at the point b and this is given as 0 and here also we assumed that all these boundary conditions are linearly independent.

(Refer Slide Time: 14:10)

Definition

Green's function $G(x, \xi)$ of the BVP (33)-(34) is constructed as:

- $G(x, \xi)$ is continuous and has continuous derivatives with respect to x upto order $(n - 2)$ inclusive for $a \leq x \leq b$.
- Its $(n - 1)$ th derivative with respect to x at the point $x = \xi$ has the discontinuity of first kind where the jump is $\frac{1}{\rho_0(x)}$, i.e.

$$\frac{\partial^{n-1} G(x, \xi)}{\partial x^{n-1}} \Big|_{x=\xi+} - \frac{\partial^{n-1} G(x, \xi)}{\partial x^{n-1}} \Big|_{x=\xi-} = \frac{1}{\rho_0(\xi)}. \quad (35)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 17

So for this we construct our Green function satisfying these following condition, so first condition is that $G(x, \xi)$ is continuous and its n minus 2th derivative is also continuous in this interval a to b , right. And its n minus 1th derivative has a jump discontinuity of order 1 by $\rho_0(\xi)$.

(Refer Slide Time: 14:36)

- In each of the intervals $[a, \xi)$ and $(\xi, b]$,

$$L[G] = 0. \quad (36)$$

- G satisfies the boundary conditions (34)

$$V_k(G) = 0 \quad (k = 1, 2, \dots, n). \quad (37)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 18

Construction of Green's Function for Ordinary Differential Equations

Suppose we have a linear differential equation of order n :

$$L[y] \equiv p_0(x)y^n + p_1(x)y^{(n-1)} + \dots + p_n(x)y = 0, \quad (33)$$

where all the coefficients are continuous on $[a, b]$, $p_0(x) \neq 0$ on $[a, b]$, and the boundary conditions are

$$V_k(y) := \alpha_k y(a) + \alpha_k^1 y'(a) + \dots + \alpha_k^{n-1} y^{(n-1)}(a) + \beta_k y(b) + \beta_k^1 y'(b) + \dots + \beta_k^{n-1} y^{(n-1)}(b) = 0, \quad k = 1, 2, \dots, n. \quad (34)$$

where the linear forms V_1, \dots, V_n in $y(a), y'(a), \dots, y^{(n-1)}(a), y(b), \dots, y^{(n-1)}(b)$ are linearly independent.

And third condition is that this Green function satisfy the linear differential operator that is $L G$. So it means that G is a solution of linear differential operator $L G$ equal to 0 when x_i is not equal to x . So it means that in each interval a to x_i and x_i to b $L G$ is the solution of this operator L , so $L G$ is equal to 0 when interval is a to x_i and x_i to b . And last condition is that G satisfy the boundary condition given as this given by this $V_k y$ equal to this.

(Refer Slide Time: 15:18)

Theorem 1

If the boundary value problem (33)-(34) has only a trivial solution $y(x) \equiv 0$, then the operator L has one and only one Green's function $G(x, \xi)$.

Proof:

Let $y_1(x), y_2(x), \dots, y_n(x)$ be L.I. solutions of the equation $L[y] = 0$. Then on the intervals $[a, \xi]$ and $[\xi, b]$, G can be written as:

$$G(x, \xi) = \sum_{i=1}^n a_i y_i(x) \text{ for } [a, \xi],$$

$$\text{and } G(x, \xi) = \sum_{i=1}^n b_i y_i(x) \text{ for } (\xi, b].$$

Construction of Green's Function for Ordinary Differential Equations

Suppose we have a linear differential equation of order n :

$$L[y] \equiv p_0(x)y^n + p_1(x)y^{(n-1)} + \dots + p_n(x)y = 0, \quad (33)$$

where all the coefficients are continuous on $[a, b]$, $p_0(x) \neq 0$ on $[a, b]$, and the boundary conditions are

$$V_k(y) := \alpha_k y(a) + \alpha_k^1 y'(a) + \dots + \alpha_k^{n-1} y^{(n-1)}(a) + \beta_k y(b) + \beta_k^1 y'(b) + \dots + \beta_k^{n-1} y^{(n-1)}(b) = 0, \quad k = 1, 2, \dots, n. \quad (34)$$

where the linear forms V_1, \dots, V_n in $y(a), y'(a), \dots, y^{(n-1)}(a), y(b), \dots, y^{(n-1)}(b)$ are linearly independent.

So here we have a theorem which says that if the boundary value problem this boundary value problem which we have defined here by 33 this is a differential equation and 34 is the boundary condition, this if this problem have only a trivial solution then the operator L has one and only one Green function $G(x, \xi)$ so that we are going to define.

So starting let us start the proof of this, so here we assume that let $y_1(x), y_2(x), \dots, y_n(x)$ are L linearly independent solution of equation $L y = 0$. Then as such state that we can write down $G(x, \xi)$ as this summation $i = 1$ to n $\alpha_i y_i(x)$ for $a < \xi < x < b$ and $G(x, \xi)$ as linear combination of these solutions in ξ, b because we already known we already know that G is going to be a solution of the operator L in this particular interval.

So it means that G can be written as linear combination of these n solution y_1 to y_n . So that is why $G(x, \xi)$ is written as linear combination of y_1 to y_n in this interval and similarly here $G(x, \xi)$ as linear combination of these solutions in this ξ, b we need to find out our α_i and β_i so that this will actually solve solve the purpose.

(Refer Slide Time: 16:50)

By the virtue of continuity of $G(x, \xi)$ and its derivatives with respect to x at the point ξ , we have:

$$\sum_{i=1}^n b_i y_i(\xi) - \sum_{i=1}^n a_i y_i(\xi) = 0$$

$$\sum_{i=1}^n b_i y_i'(\xi) - \sum_{i=1}^n a_i y_i'(\xi) = 0$$

$$\vdots \quad \quad \quad \vdots$$

$$\sum_{i=1}^n b_i y_i^{(n-2)}(\xi) - \sum_{i=1}^n a_i y_i^{(n-2)}(\xi) = 0$$

$$\sum_{i=1}^n b_i y_i^{(n-1)}(\xi) - \sum_{i=1}^n a_i y_i^{(n-1)}(\xi) = \frac{1}{\rho_0(\xi)}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 20

So now here we apply the condition that $G(x, \xi)$ is continuous and its derivative upto order n minus 2 is continuous if you look at the first condition simply says that $G(x, \xi)$ has continuity at x equal to ξ and this still here we have assumed that n minus 2th derivative of G has a continuity at x equal to ξ .

(Refer Slide Time: 17:30)

$$G(x, \xi) = \sum_{i=1}^n a_i y_i(x) \quad x \in [a, \xi)$$

$$G(x, \xi) = \sum_{i=1}^n b_i y_i(x) \quad x \in (\xi, b]$$

$$L(G) = 0, \quad x \neq \xi.$$

$$G(x, \xi) \text{ is cont at } x = \xi. \quad \sum_{i=1}^n b_i y_i(x) \Big|_{x=\xi} = \sum_{i=1}^n a_i y_i(x) \Big|_{x=\xi}$$

$$G'(x, \xi) \text{ is also cont at } x = \xi.$$

$$G^{(n-2)}(x, \xi) \text{ is also cont at } x = \xi. \quad \sum_{i=1}^n b_i y_i^{(n-2)}(x) \Big|_{x=\xi} = \sum_{i=1}^n a_i y_i^{(n-2)}(x) \Big|_{x=\xi}$$

$$G^{(n-1)}(x, \xi) \Big|_{x=\xi^+} - G^{(n-1)}(x, \xi) \Big|_{x=\xi^-} = \frac{1}{\rho_0(\xi)}$$

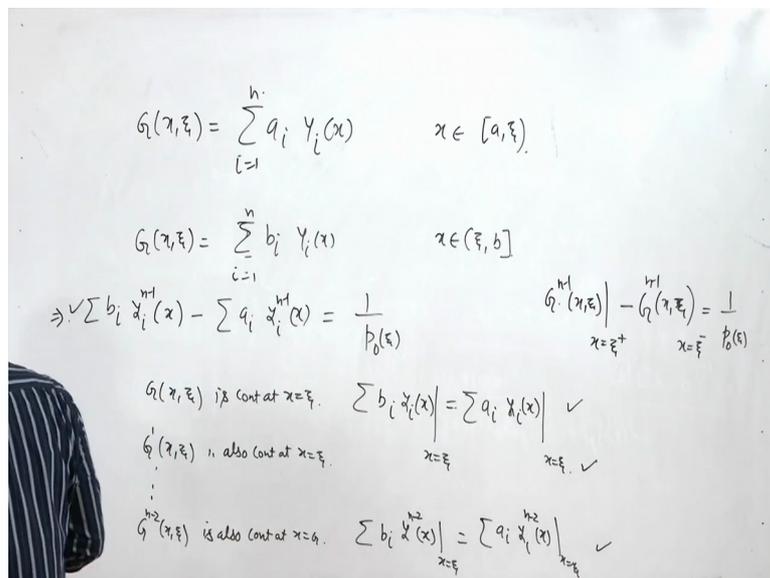

So if you look at here so here we have assumed that $G(x, \xi)$ is equal to summation $a_i y_i(x)$ and i equal to 1 to n between x is between your a to ξ and $G(x, \xi)$ is equal to summation i equal to 1 to n $b_i y_i(x)$ between x is lying between ξ to b here. So this we can this we have a (18:03) by saying that L of G is equal to 0 for x not equal to ξ , right. Now if we use the condition that that $G(x, \xi)$ is continuous at x equal to ξ it means that they should match as x

equal to x_i , so right hand limit is equal to left hand limit so we can write it summation $b_i y_i$ at $x = x_i$ is equal to summation $a_i y_i$ at $x = x_i$.

Similarly we G dash x, x_i is also continuous at $x = x_i$ and so on upto $n - 2$ th derivative of this, so $n - 2$ th derivative of G is also continuous at $x = x_i$. So this implies that summation $b_i y_i^{n-2}$ at $x = x_i$ is equal to summation $a_i y_i^{n-2}$ at $x = x_i$ so is same here, okay.

Then last condition is that it has a jump discontinuity of order of magnitude 1 upon p not x_i . Here it is x, x_i at $x = x_i$ plus minus G $n - 1$ th derivative of x, x_i evaluated at $x = x_i$ minus is equal to 1 upon p not x_i .

(Refer Slide Time: 20:02)

So if we use this then we have one more condition written as this, so here we can write down this condition that summation $b_i y_i^{n-1}$ at $x = x_i$ minus summation $a_i y_i^{n-1}$ at $x = x_i$ is equal to 1 upon p not x_i , right. So here we have one condition and here we have these many conditions.

(Refer Slide Time: 20:46)

By the virtue of continuity of $G(x, \xi)$ and its derivatives with respect to x at the point ξ , we have:

$$\begin{aligned} \sum_{i=1}^n b_i y_i(\xi) - \sum_{i=1}^n a_i y_i(\xi) &= 0 \\ \sum_{i=1}^n b_i y_i'(\xi) - \sum_{i=1}^n a_i y_i'(\xi) &= 0 \\ \vdots & \quad \quad \quad \vdots \\ \sum_{i=1}^n b_i y_i^{(n-2)}(\xi) - \sum_{i=1}^n a_i y_i^{(n-2)}(\xi) &= 0 \\ \sum_{i=1}^n b_i y_i^{(n-1)}(\xi) - \sum_{i=1}^n a_i y_i^{(n-1)}(\xi) &= \frac{1}{\rho_0(\xi)} \end{aligned}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 20

On putting $c_k(\xi) = b_k(\xi) - a_k(\xi)$ then,

$$\begin{aligned} \sum_{i=1}^n c_i y_i(\xi) &= 0 \\ \sum_{i=1}^n c_i y_i'(\xi) &= 0 \\ \vdots & \quad \quad \quad \vdots \\ \sum_{i=1}^n c_i y_i^{(n-2)}(\xi) &= 0 \\ \sum_{i=1}^n c_i y_i^{(n-1)}(\xi) &= \frac{1}{\rho_0(\xi)} \end{aligned} \tag{38}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 21

So all these condition we can write it in this particular form and look at here here we have all such condition. So first these still here we have assumed that G has continuity upto order n minus 2th derivative and this last represent the that n minus 1th derivative of G has jump of size 1 upon p not ξ . So here this can be made simplify by writing b_i minus c_i , b_i minus c_i as some other variable that is c_i .

So here we assume that your $c_k \xi$ equal to $b_k \xi$ minus $a_k \xi$ and if we assume this then this can be written in a this simpler form, okay. Now what we try to have is that we try to find out all these constant a_i and b_i , so first what we try to do is we first find out this c_i and with the help of c_i we try to find out both b_i and a_i . So if you look at this represent linear differential equation $Ax = B$, so if you look at equation system of equation given as 38.

(Refer Slide Time: 22:02)

$$c_1 y_1(x) + c_2 y_2(x) + c_3 y_3(x) + \dots + c_n y_n(x) = 0$$

$$c_1 y_1'(x) + \dots + c_n y_n'(x) = 0$$

$$\vdots$$

$$c_1 y_1^{(n-1)}(x) + \dots + c_n y_n^{(n-1)}(x) = \frac{1}{p(x)}$$

$$A \begin{bmatrix} c_1 \\ \vdots \\ c_n \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ \frac{1}{p(x)} \end{bmatrix}, \text{ where } A = \begin{bmatrix} y_1(x) & y_2(x) & \dots & y_n(x) \\ y_1'(x) & y_2'(x) & \dots & y_n'(x) \\ \vdots & \vdots & \ddots & \vdots \\ y_1^{(n-1)}(x) & y_2^{(n-1)}(x) & \dots & y_n^{(n-1)}(x) \end{bmatrix} = A(y_1, y_2, \dots, y_n)(x)$$

$$\Rightarrow \begin{bmatrix} c_1 \\ \vdots \\ c_n \end{bmatrix} = A^{-1} \begin{bmatrix} 0 \\ 0 \\ \vdots \\ \frac{1}{p(x)} \end{bmatrix}$$

So here we can write it like this so here we have $c_1 y_1(x) + c_2 y_2(x) + c_3 y_3(x) + \dots + c_n y_n(x) = 0$. And second equation is $c_1 y_1'(x) + \dots + c_n y_n'(x) = 0$ and so on last one is $c_1 y_1^{(n-1)}(x) + \dots + c_n y_n^{(n-1)}(x) = \frac{1}{p(x)}$. So this I can write it as A into this is your c_1 to c_n equal to this $0, 0$ upto 1 upon $p(x)$, where this A is given as this $y_1(x), y_2(x)$ and $y_n(x)$ and $y_1'(x), y_2'(x)$ and $y_n'(x)$ and so on, last one is $y_1^{(n-1)}(x), y_2^{(n-1)}(x)$ and so on.

And if you remember that this is nothing but the $(())(23:58)$ of y_1, y_2 and so on upto y_n evaluated at x .

Now here since in the beginning itself we have assumed that y_1 to y_n are all linearly independent solution. So this means that this determinant of this coefficient matrix A is (going to be nonzero) going to be $\neq 0$. So it means that this implies that this will have a unique solution. So I can get our solution c_1 to c_n by saying A inverse operating on 0 to 1 upon $p(x)$, so it means that with the help of these conditions we can actually find out the solution for this c_1 to c_n .

(Refer Slide Time: 25:10)

The determinant of coefficient matrix of the system (38) is Wronskian $W(y_1(\xi), y_2(\xi), \dots, y_n(\xi))$ at $x = \xi$ which is non-zero. Therefore the system (38) has unique solution. To find $a_k(\xi)$ and $b_k(\xi)$ we will use boundary condition (34).
 Writing $V_k(y)$ as

$$V_k(y) = A_k(y) + B_k(y), \quad (39)$$

where $A_k(y) = \alpha_k y(a) + \alpha_k^1 y'(a) + \dots + \alpha_k^{n-1} y^{(n-1)}(a)$,
 and $B_k(y) = \beta_k y(b) + \beta_k^1 y'(b) + \dots + \beta_k^{n-1} y^{(n-1)}(b)$.

Then since

$$V_k(G) = 0 \quad \forall k = 1, 2, \dots, n, \text{ where}$$

$$V_k(G) = a_1 A_k(y_1) + a_2 A_k(y_2) + \dots + a_n A_k(y_n) + b_1 B_k(y_1) + b_2 B_k(y_2) + \dots + b_n B_k(y_n)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 22

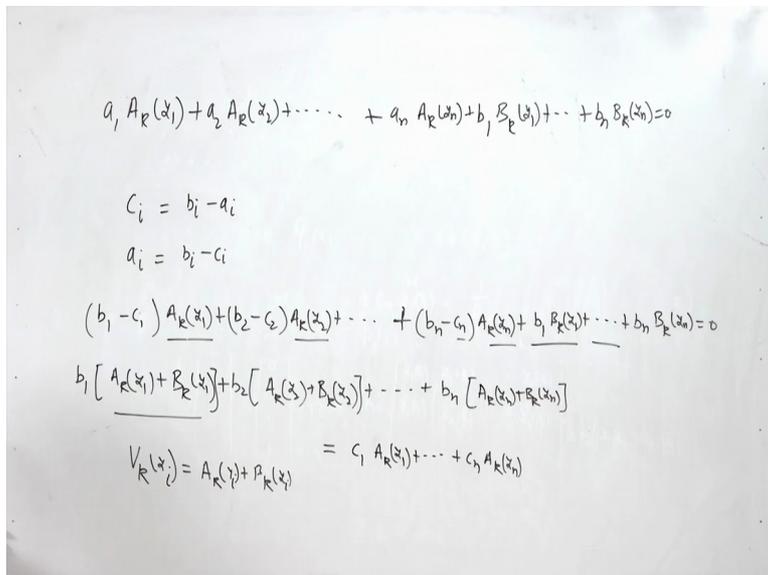

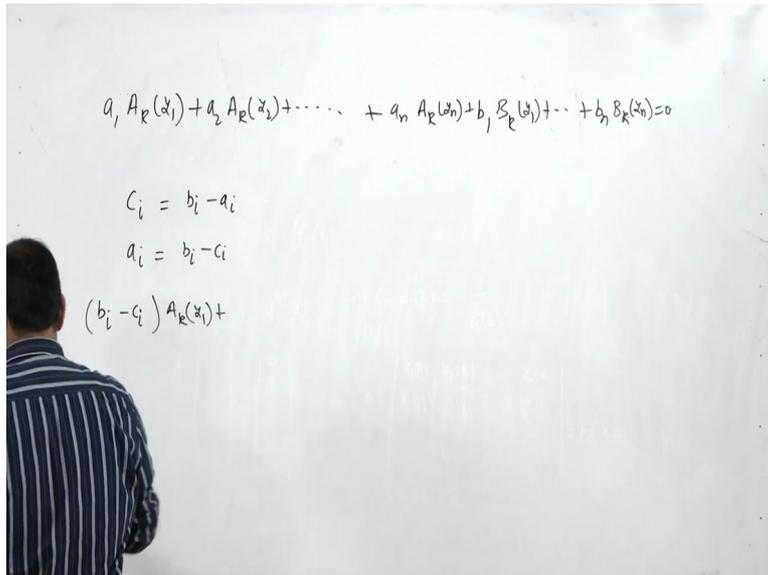

But we want to find out a_1 to a_n and b_1 to b_n not c_1 to c_n . So what we do is we need to find out our coefficient a_i and because i with the help of c_i . For this we assume here that we know that this $V_k y$ can be written as $A_k y$ plus $B_k y$, where we have separated the boundary condition at A and B , so this $A_k y$ represent the boundary condition given at the end point A and $B_k y$ represent the boundary condition given at the point B .

So we already know that Green function is going to satisfy the boundary condition, so here $V_k G$ is equal to 0, so if we simplify I can write this $V_k G$ as $a_1 A_k y_1$ plus $a_2 A_k y_2$ and so on plus $b_1 B_k y_1$ plus $b_2 B_k y_2$ and this thing and this is going to be 0.

(Refer Slide Time: 26:00)

$$a_1 A_k(x_1) + a_2 A_k(x_2) + \dots + a_n A_k(x_n) + b_1 B_k(x_1) + \dots + b_n B_k(x_n) = 0$$

$$a_i = c_i - b_i$$

So here if you look at this here we have this $a_1 A_k y_1$ plus $a_2 A_k y_2$ and so on $a_n A_k y_n$ is equal to sorry plus $b_1 B_k y_1$ and so on $b_n B_k y_n$ is equal to 0. So what we know here that I can write $(a_k) a_i$ as c_i minus b_i , okay (no) c_i we have assumed here c_i as your b_i minus a_i , so I can write it here your a_i as b_i minus c_i . So if we use this then I can write it here b_i minus $c_i A_k y_1$ plus sorry this is I am writing for a 1 so it is b_1 minus c_1 , so it is b_1 minus $c_1 A_k y_1$ plus b_2 minus $c_2 A_k y_2$ and so on it is b_n minus c_n this $A_k y_n$ plus $b_1 B_k y_1$ and so on.

Now here if we look at this I can simplify as b_1 and I can write it here $A_k y_1$ plus b_k this is your $A_k y_1$ and I can write it here $B_k y_1$, so I can write b_1 as $b_1 A_k y_1$ plus $B_k y_1$. Similarly coefficient of b_2 I can write it here $A_k y_2$ and I can write it here the $B_k y_2$ and

so on till b_n equal b_n coefficient of b_n as $A_k y_n$ plus $B_k y_n$ is equal to so this we are going to other side so it is $c_1 A_k y_1$ and till $c_n A_k y_n$.

Now this is what this $A_k y_1$ plus $B_k y_1$ we have assumed that this is nothing but your $V_k y_1$, so here $V_k y$ is defined as $A_k y$ plus $B_k y$. So $V_k y$ is defined as $A_k y$ plus $B_k y$, so I can say that $V_k y_i$ is defined as $A_k y_i$ and $B_k y_i$.

(Refer Slide Time: 29:30)

Putting $a_k = b_k - c_k$ and by use of equation (39), we get

$$b_1 V_k(y_1) + b_2 V_k(y_2) + \dots + b_n V_k(y_n) = c_1 A_k(y_1) + c_2 A_k(y_2) + \dots + c_n A_k(y_n) \quad \forall k \quad (40)$$

The determinant of the system (40) is non-zero by virtue of the linear independence of the forms V_1, V_2, \dots, V_n . Consequently we get unique $b_k(\xi)$'s and hence unique $a_k(\xi)$'s $\forall k = 1, 2, \dots, n$.

$$b_1 V_k(x_1) + b_2 V_k(x_2) + \dots + b_n V_k(x_n) = c_1 A_k(x_1) + \dots + c_n A_k(x_n)$$

$$\begin{matrix}
 V_1(x_1) & V_1(x_2) & \dots & V_1(x_n) \\
 V_2(x_1) & V_2(x_2) & \dots & V_2(x_n) \\
 \vdots & \vdots & \ddots & \vdots \\
 V_n(x_1) & V_n(x_2) & \dots & V_n(x_n)
 \end{matrix}
 \begin{bmatrix} b_1 \\ \vdots \\ b_n \end{bmatrix} = \begin{matrix}
 A_1(x_1) & \dots & A_1(x_n) \\
 \vdots & & \vdots \\
 A_n(x_1) & \dots & A_n(x_n)
 \end{matrix}
 \begin{bmatrix} c_1 \\ \vdots \\ c_n \end{bmatrix}$$

$k = 1, 2, \dots, n$

$$b_1 [A_k(x_1) + B_k(x_1)] + b_2 [A_k(x_2) + B_k(x_2)] + \dots + b_n [A_k(x_n) + B_k(x_n)] = c_1 A_k(x_1) + \dots + c_n A_k(x_n)$$

$$V_k(x_i) = A_k(x_i) + B_k(x_i)$$

So I can write this as this relation that $b_1 V_k y_1$ plus $b_2 V_k y_2$ and so on. Now if you look at here this is again forming a linear differential equation in terms of b_1 to b_n , right and coefficient matrix is what coefficient matrix is given as let me write it here. So here I am just writing here. So here this is what this is $b_1 V_k y_1$ plus $b_2 V_k y_2$ and so on $b_n V_k y_n$ is equal to your $c_1 A_k y_1$ and so on $c_n A_k y_n$, so if we and here k is from 1 to n .

So if we write it for each one I can write it this as $(V_1 y_1 + \dots + V_k y_k)$ sorry $V_1 y_1$ I am writing for the same equation for k equal to 1. So it is $V_1 y_1, V_2 y_2$ and so on $V_1 y_n$, so this is V_1 here so for k equal to 1, I am writing it in a system of linear equation format. So here first row is $V_1 y_1, V_1 y_2$ and so on. Second is $V_2 y_1, V_2 y_2$ and $V_2 y_n$ and last is $V_n y_1, V_n y_2$ and $V_n y_n$ and here your $A_1 y_1$ to $A_1 y_n$ and here it is under dash here we have $A_n y_1$ to $A_n y_n$.

Now we already assumed here that these $V_k y_1$ all these linear forms are linearly independent. So it means that this coefficient matrix has nonzero determinant. So if it has a nonzero determinant then we can find out a unique solution by inverting this coefficient matrix here.

(Refer Slide Time: 32:36)

The image shows a whiteboard with the following content:

$$b_1 V_1(x_1) + b_2 V_1(x_2) + \dots + b_n V_1(x_n) = c_1 A_1(x_1) + \dots + c_n A_1(x_n)$$

$i = 1, 2, \dots, n$

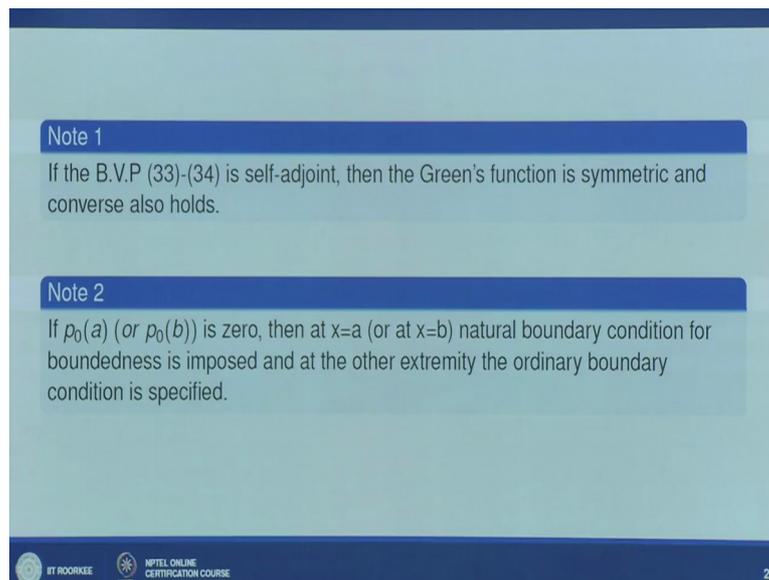

$$\begin{bmatrix} V_1(x_1) & V_1(x_2) & \dots & V_1(x_n) \\ V_2(x_1) & V_2(x_2) & \dots & V_2(x_n) \\ \vdots & \vdots & \ddots & \vdots \\ V_n(x_1) & V_n(x_2) & \dots & V_n(x_n) \end{bmatrix} \begin{bmatrix} b_1 \\ \vdots \\ b_n \end{bmatrix} = \begin{bmatrix} A_1(x_1) & \dots & A_1(x_n) \\ \vdots & \ddots & \vdots \\ A_n(x_1) & \dots & A_n(x_n) \end{bmatrix} \begin{bmatrix} c_1 \\ \vdots \\ c_n \end{bmatrix}$$

$b_i = ??$ c_i $i = 1, \dots, n$

$$b_i - c_i = a_i \Rightarrow a_i = b_i - c_i$$

So it means we can find out say unique solution for these coefficient b_1 to b_n . So with this system of linear equation we can find out b_i we can calculate this and we already know what is c_i for i equal to 1 to n . So it means that once we know b_i and c_i you can already get a_i as b_i minus a_i is equal to c_i , so we know c_i , we know b_i so we can get our a_i as b_i minus c_i and hence our Green function is known for this particular problem.

(Refer Slide Time: 33:14)

The slide features a light blue background with two dark blue rectangular boxes containing text. The first box is titled 'Note 1' and the second is titled 'Note 2'. At the bottom of the slide, there is a dark blue footer bar containing logos for IIT Roorkee and NPTEL Online Certification Course, along with the page number 24.

Note 1
If the B.V.P (33)-(34) is self-adjoint, then the Green's function is symmetric and converse also holds.

Note 2
If $p_0(a)$ (or $p_0(b)$) is zero, then at $x=a$ (or at $x=b$) natural boundary condition for boundedness is imposed and at the other extremity the ordinary boundary condition is specified.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 24

So we can get all coefficient with all these conditions, right. So now next is that if this boundary value problem is self adjoint then your Green function is going to be symmetric and it is converses also true and here it may happen that the highest order coefficient of highest order derivative is going to vanish at say one of the end point say A or B. In that particular case we will assume one natural condition that your solution is going to be bounded at that particular end.

For example if I assume that p not A is 0 then we assume that our solution is going to be bounded at x equal to A. So what we have done here in this particular lecture we have generalized the concept of construction of Green function for n th order linear differential equation. So thanks for listening us.
