Classical Fredholm Theory Fredholm Second and Third Theorem

(Refer Slide Time 00:18)

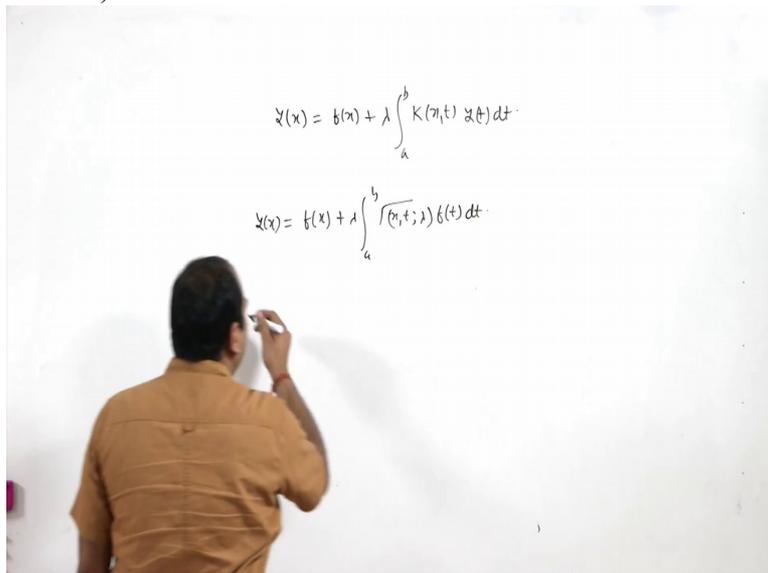

Hello friends, welcome to the today's lecture. Please recall that in previous class we have, previous lecture we have discussed the solution method for this kind of Fredholm integral equation of y of x equal to f of x plus λ , a to b K of x of t y of t $d t$ and we have

(Refer Slide Time 00:45)

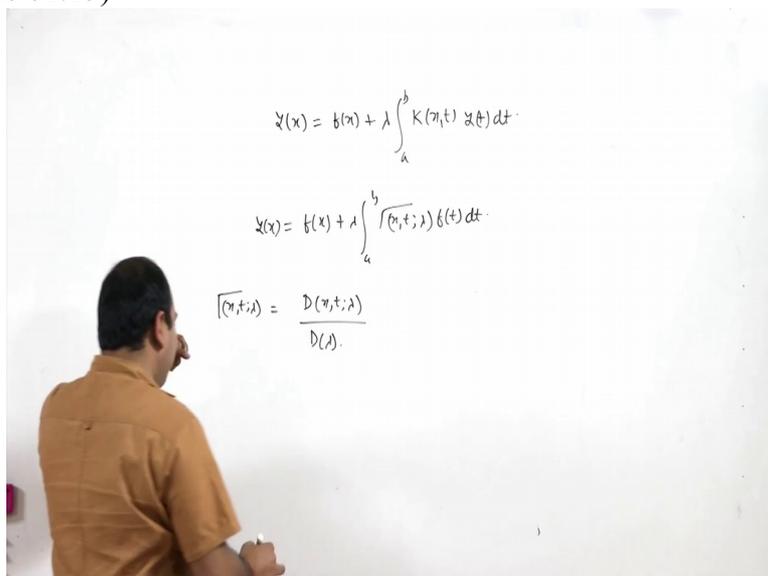

seen that the solution can be written as y of x equal to f of x plus a to b λ γ x of t λ f of t $d t$

(Refer Slide Time 01:03)

and where $\gamma(x,t;\lambda)$ is given as $D(x,t;\lambda)$ divided by $D(\lambda)$.

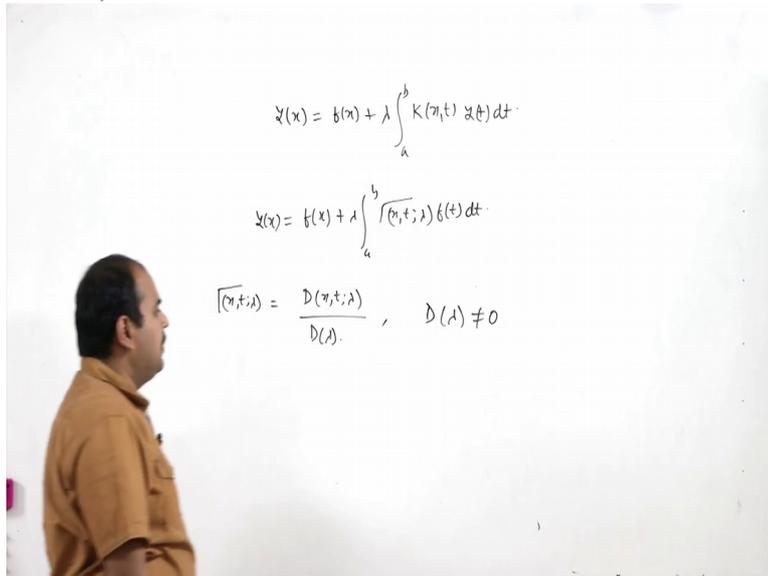

(Refer Slide Time 01:15)

So it means that the solution of the given Fredholm integral equation can be given by y of x where $\gamma(x,t;\lambda)$ is a resolvent kernel given by this ratio of two infinite series.

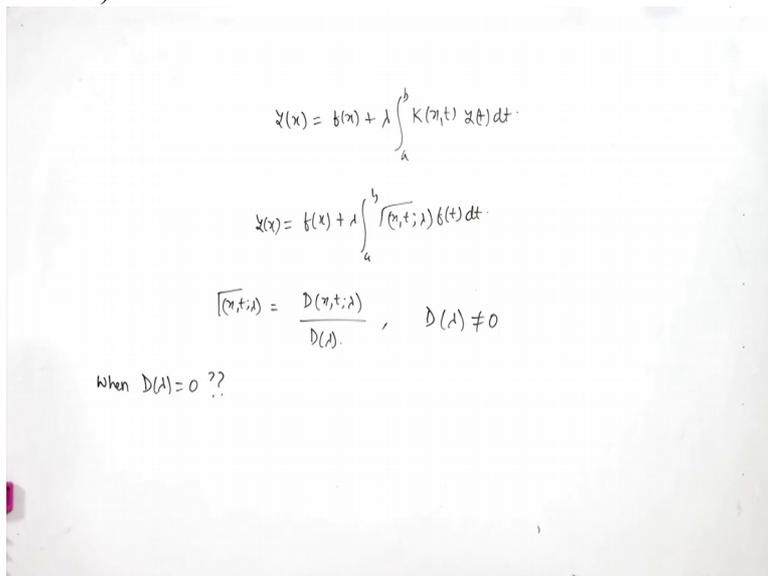

But the problem arises when this λ , this λ is coming out to be the root of $D(\lambda)$. Or you can say the solution is valid when $D(\lambda)$ is not equal to zero for this λ .

(Refer Slide Time 01:45)

But when D lambda is equal to zero then how we can define our solution? Then please

(Refer Slide Time 01:55)

recall, then our D once we know the D lambda then your D of x t lambda is defined as, by this following relation that K of x t D of lambda plus a to b K of x of s D of x s of t lambda, s t lambda d t here. We know that when

(Refer Slide Time 02:30)

$$\begin{aligned} \psi(x) &= b(x) + \lambda \int_a^b K(x,t) \psi(t) dt \\ \psi(x) &= b(x) + \lambda \int_a^b \overline{K(x,t;\lambda)} f(t) dt \\ \overline{K(x,t;\lambda)} &= \frac{D(x,t;\lambda)}{D(\lambda)}, \quad D(\lambda) \neq 0 \\ \text{When } D(\lambda) = 0 \text{ ??} \\ D(x,t;\lambda) &= K(x,t) D(\lambda) + \lambda \int_a^b K(x,s) D(s,t;\lambda) dt \end{aligned}$$

once we have expression for D lambda that is Fredholm determinant then we have calculated the Fredholm minor that is D x t lambda with the help of this integral equation. This is a relation hold by D of x t lambda and then we have seen that if D of lambda, this we have already done that if D lambda is given by c naught plus summation minus lambda to power m upon factorial m, c m m is from 1 to infinity, then with the help of

(Refer Slide Time 03:04)

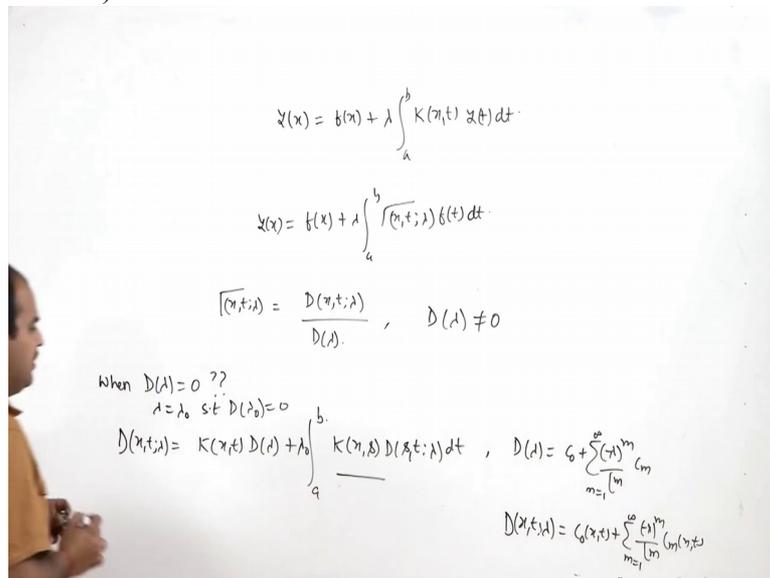

$$\begin{aligned} \psi(x) &= b(x) + \lambda \int_a^b K(x,t) \psi(t) dt \\ \psi(x) &= b(x) + \lambda \int_a^b \overline{K(x,t;\lambda)} f(t) dt \\ \overline{K(x,t;\lambda)} &= \frac{D(x,t;\lambda)}{D(\lambda)}, \quad D(\lambda) \neq 0 \\ \text{When} \\ D(x,t;\lambda) &= K(x,t) D(\lambda) + \lambda \int_a^b K(x,s) D(s,t;\lambda) dt, \quad D(\lambda) = c_0 + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} c_m \end{aligned}$$

this integral equation we try to find out, we have already discussed that D of x t lambda you can calculate c naught of x of t plus summation m is equal to 1 to infinity minus lambda to power m upon factorial m c m x of t. So it means that this, with the help of this equation and the expression of D lambda we have to, we have calculated the expression for D x t lambda and also we have seen that if the kernel K is integrable and bounded then expression given as

D lambda is an uniform, uniform series in terms of lambda for all values of lambda. Similarly you can say that in the condition that this kernel is integrable and bounded then D x t lambda is also, this infinite series is also uniformly convergent for all values of lambda here. So this we have already discussed.

Now the case with the help of this equation only, we try to consider the case when D lambda is equal to zero. It means that let us say that you have a value lambda equal to lambda naught such that D lambda naught is equal to zero. So it means that here

(Refer Slide Time 04:31)

we are taking the value lambda naught. So here for this particular value, your D lambda naught is simply zero. I am just considering the value lambda equal to lambda naught. So this part is simply vanished. So you can write it D of x t lambda naught is equal to lambda naught a to b K of x of s D of s t lambda naught d of t.

(Refer Slide Time 05:02)

$$y(x) = b(x) + \lambda \int_a^b K(x,t) y(t) dt$$

$$y(x) = f(x) + \lambda \int_a^b \overline{K(x,t;\lambda)} f(t) dt$$

$$\overline{K(x,t;\lambda)} = \frac{D(x,t;\lambda)}{D(\lambda)}, \quad D(\lambda) \neq 0$$

When $D(\lambda) = 0$??
 $\lambda = \lambda_0$ s.t. $D(\lambda_0) = 0$

$$D(x,t;\lambda) = K(x,t) D(\lambda) + \lambda_0 \int_a^b K(x,s) D(s,t;\lambda_0) ds, \quad D(\lambda) = c_0 + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} c_m$$

$$D(x,t;\lambda_0) = \lambda_0 \int_a^b K(x,s) D(s,t;\lambda_0) ds, \quad D(x,t;\lambda) = c_0(x,t) + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} c_m(x,t)$$

Is that Ok? Now I am saying that first we will consider the case when f of x is equal to zero, means that we are considering the homogenous part. So here we are considering that when λ is equal to zero and we are assuming that f of x is equal to zero. So it means that

(Refer Slide Time 05:23)

$$y(x) = b(x) + \lambda \int_a^b K(x,t) y(t) dt$$

$$y(x) = f(x) + \lambda \int_a^b \overline{K(x,t;\lambda)} f(t) dt$$

$$\overline{K(x,t;\lambda)} = \frac{D(x,t;\lambda)}{D(\lambda)}, \quad D(\lambda) \neq 0$$

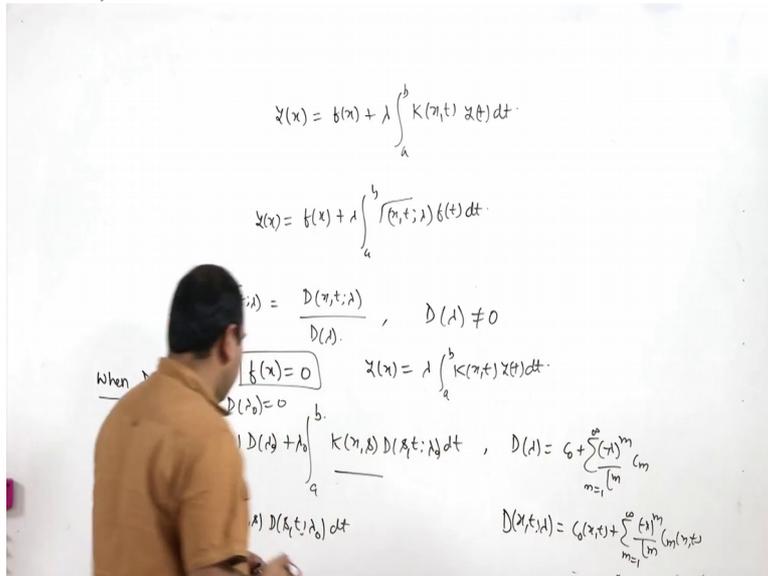

When $D(\lambda) = 0$?? $\boxed{f(x) = 0}$
 $\lambda = \lambda_0$ s.t. $D(\lambda_0) = 0$

$$D(x,t;\lambda) = K(x,t) D(\lambda) + \lambda_0 \int_a^b K(x,s) D(s,t;\lambda_0) ds, \quad D(\lambda) = c_0 + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} c_m$$

$$D(x,t;\lambda_0) = \lambda_0 \int_a^b K(x,s) D(s,t;\lambda_0) ds, \quad D(x,t;\lambda) = c_0(x,t) + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} c_m(x,t)$$

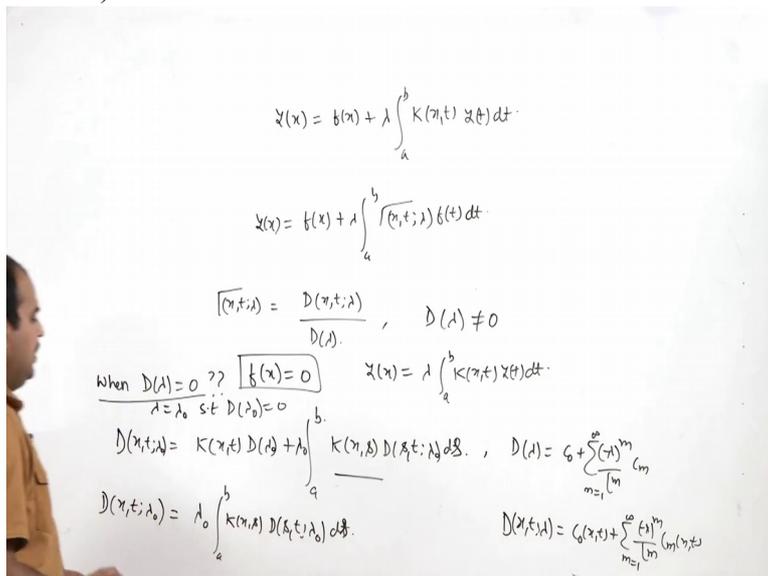

we are considering only the homogenous part. Then we say that in this case your equation is this; y of x equal to λ a to b K of x of t y of t $d t$, right?

(Refer Slide Time 05:39)

Ok. So this small correction here. This correction is this, that here this integral is with respect to s not with respect to t. So here integration is with respect to d of s. So here is d of s.

(Refer Slide Time 06:03)

Ok, so here if we compare the equation and this equation, so if we compare these two equations you can see that here if I assume that $D \times t \lambda$ naught is not non-zero, identically not equal to zero

(Refer Slide Time 06:23)

$$y(x) = b(x) + \lambda \int_a^b K(x,t) y(t) dt$$

$$y(x) = b(x) + \lambda \int_a^b \overline{K(x,t;\lambda)} b(t) dt$$

$$\overline{K(x,t;\lambda)} = \frac{D(x,t;\lambda)}{D(\lambda)}, \quad D(\lambda) \neq 0$$

When $D(\lambda) = 0$?? $\boxed{b(x) = 0}$ $y(x) = \lambda \int_a^b K(x,t) y(t) dt$

$$D(x,t;\lambda) = K(x,t) D(\lambda) + \lambda_0 \int_a^b K(x,s) D(s,t;\lambda) ds, \quad D(\lambda) = C_0 + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} C_m$$

$$D(x,t;\lambda_0) = \lambda_0 \int_a^b K(x,s) D(s,t;\lambda_0) ds, \quad D(x,t;\lambda) = C_0(x,t) + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} C_m(x,t)$$

$$D(x,t;\lambda_0) \neq 0$$

then I can assume that y of x is equal to

(Refer Slide Time 06:28)

$$y(x) = b(x) + \lambda \int_a^b K(x,t) y(t) dt$$

$$y(x) = b(x) + \lambda \int_a^b \overline{K(x,t;\lambda)} b(t) dt$$

$$\overline{K(x,t;\lambda)} = \frac{D(x,t;\lambda)}{D(\lambda)}, \quad D(\lambda) \neq 0$$

When $D(\lambda) = 0$?? $\boxed{b(x) = 0}$ $y(x) = \lambda \int_a^b K(x,t) y(t) dt$

$$D(x,t;\lambda) = K(x,t) D(\lambda) + \lambda_0 \int_a^b K(x,s) D(s,t;\lambda) ds, \quad D(\lambda) = C_0 + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} C_m$$

$$D(x,t;\lambda_0) = \lambda_0 \int_a^b K(x,s) D(s,t;\lambda_0) ds, \quad D(x,t;\lambda) = C_0(x,t) + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} C_m(x,t)$$

$$y(x) = D(x,t;\lambda_0) \neq 0$$

D of x t λ naught is a solution of this particular equation for every value of t in the interval a to b . Is that Ok? So

(Refer Slide Time 06:49)

$$y(x) = b(x) + \lambda \int_a^b K(x,t) y(t) dt$$

$$y(x) = b(x) + \lambda \int_a^b \overline{K(x,t;\lambda)} b(t) dt$$

$$\overline{K(x,t;\lambda)} = \frac{D(x,t;\lambda)}{D(\lambda)}, \quad D(\lambda) \neq 0$$

When $D(\lambda) = 0$?? $\int_a^b b(x) = 0$ $y(x) = \lambda \int_a^b K(x,t) y(t) dt$

$$D(x,t;\lambda) = K(x,t) D(\lambda) + \lambda_0 \int_a^b K(x,s) D(s,t;\lambda) ds, \quad D(\lambda) = \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m} C_m$$

$$D(x,t;\lambda) = \lambda_0 \int_a^b K(x,s) D(s,t;\lambda) ds$$

$$D(x,t;\lambda) = C_0(x,t) + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m} C_m(x,t)$$

$y(x) = D(x,t;\lambda_0) \neq 0 \quad \forall t \in [a,b]$

it means that this y of x equal to D of x t lambda naught is a solution of this equation for all t in this interval a to b, is it Ok? So only thing we are worried is that this expression whether this is zero or not. So this part, this decision, we can write it in this particular part that if D lambda

(Refer Slide Time 07:02)

Fredholm's Second Theorem

If $D(\lambda_0) = 0$ and $D(x, t, \lambda_0) \neq 0$, then for a proper choice of t say $t = t_0$, $y(x) = D(x, t_0, \lambda_0)$ is a continuous solution of

$$y(x) = \lambda_0 \int_a^b k(x, t) y(t) dt. \quad (47)$$

On differentiation of equation (37) and interchange the indices of the variable of integration, we obtain

$$D'(\lambda) = - \int_a^b D(x, x, \lambda) dx \quad (48)$$

Particularly, if λ_0 is a simple zero of $D(\lambda)$, then $D(\lambda_0) = 0$, $D'(\lambda_0) \neq 0$, and λ_0 is a simple pole of the resolvent kernel. Moreover, from (48), $D(x, t, \lambda) \neq 0$.

BY ROORKEE NPTEL ONLINE CERTIFICATION COURSE 39

naught is equal to zero, so here we are assuming that lambda naught is a root of this Fredholm determinant that is D lambda naught equal to zero and we also assuming that D x t lambda naught is not equal to zero, not identically equal to zero then we can choose any value of this t and we can say that y of x as D of x t naught lambda naught is a solution of this equation. That is y of x equal to lambda naught a to b K x t y t d t. So that is clear from this. So here if you compare these two equations, this and this and we can say that y of x

(Refer Slide Time 07:42)

$$z(x) = b(x) + \lambda \int_a^b K(x,t) z(t) dt$$

$$z(x) = b(x) + \lambda \int_a^b \overline{K(x,t;\lambda)} f(t) dt$$

$$\overline{K(x,t;\lambda)} = \frac{D(x,t;\lambda)}{D(\lambda)}, \quad D(\lambda) \neq 0$$

When $D(\lambda) = 0$?? $\boxed{f(x) = 0}$ $z(x) = \lambda \int_a^b K(x,t) z(t) dt$ ✓

$\lambda = \lambda_0$ s.t. $D(\lambda_0) = 0$

$$D(x,t;\lambda) = K(x,t) D(\lambda) + \lambda_0 \int_a^b K(x,s) D(s,t;\lambda) ds, \quad D(\lambda) = c_0 + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} c_m$$

$$D(x,t;\lambda_0) = \lambda_0 \int_a^b K(x,s) D(s,t;\lambda_0) ds \quad \checkmark$$

$$D(x,t;\lambda) = c_0(x,t) + \sum_{m=1}^{\infty} \frac{(-\lambda)^m}{m!} c_m(x,t)$$

$D(x,t;\lambda_0) \neq 0 \quad \forall t \in [a,b]$

equal to $D \times t \lambda$ which is not identically equal to zero is a solution of this equation.

Now the thing is that, the condition that $D \times t \lambda$ naught is not equal to zero,

(Refer Slide Time 07:57)

Fredholm's Second Theorem

If $D(\lambda_0) = 0$ and $D(x, t; \lambda_0) \neq 0$, then for a proper choice of t say $t = t_0$, $y(x) = D(x, t_0; \lambda_0)$ is a continuous solution of

$$y(x) = \lambda_0 \int k(x, t) y(t) dt. \quad (47)$$

On differentiation of equation (37) and interchange the indices of the variable of integration, we obtain

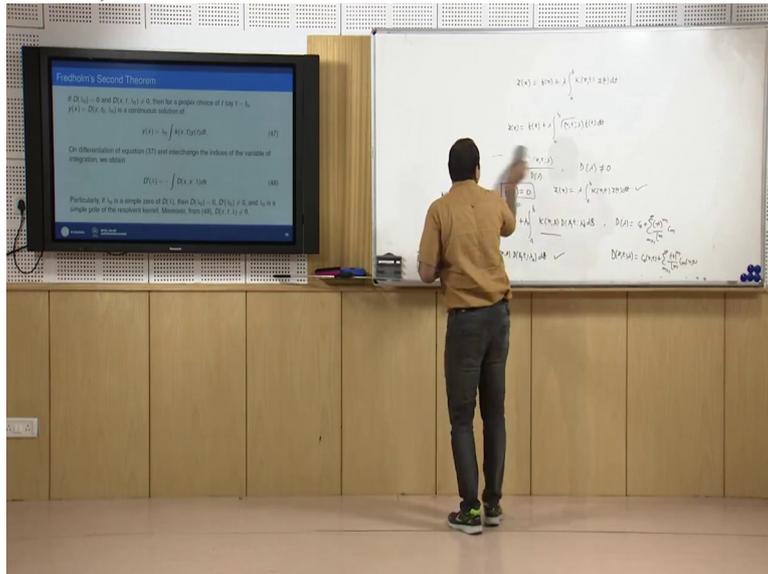

$$D'(\lambda) = - \int D(x, x; \lambda) dx \quad (48)$$

Particularly, if λ_0 is a simple zero of $D(\lambda)$, then $D(\lambda_0) = 0$, $D'(\lambda_0) \neq 0$, and λ_0 is a simple pole of the resolvent kernel. Moreover, from (48), $D(x, t; \lambda) \neq 0$.

IT ROORKEE
NPTEL ONLINE CERTIFICATION COURSE
39

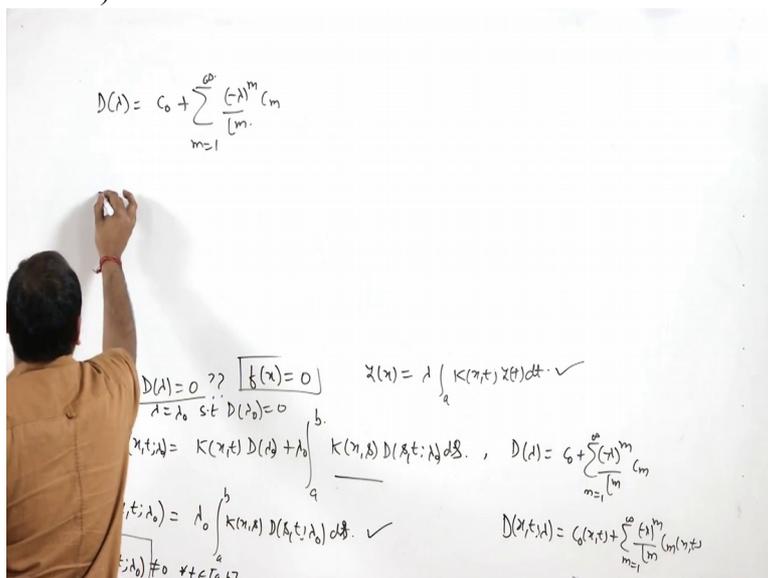

how we can say, rectify this. So this condition that $D \times t \lambda$ naught is not identically equal to zero can be related to the special Fredholm determinant $D \lambda$ in this way; that if you look at the expression of $D \lambda$ and if we differentiate that then we have this relation. So just let me see what is this relation.

(Refer Slide Time 08:22)

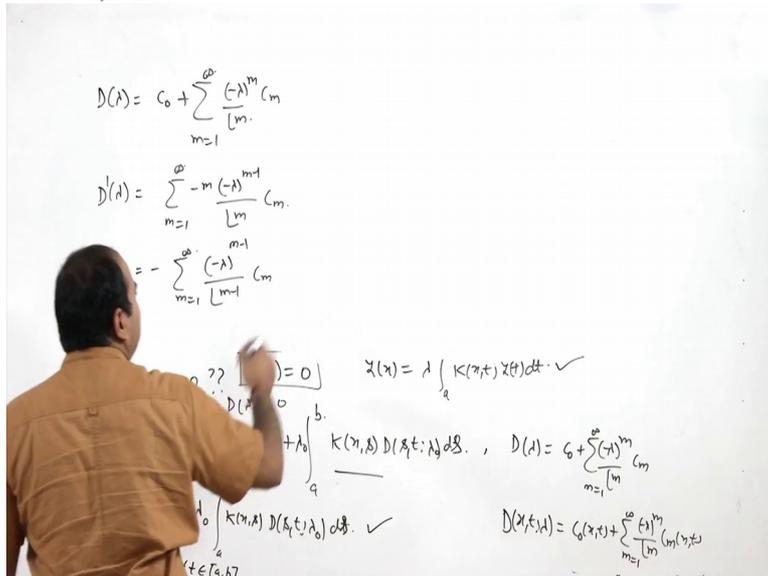

So here we have this D lambda that is small c naught plus summation m equal to 1 to infinity minus lambda to power m small c m upon factorial m. So if we differentiate this,

(Refer Slide Time 08:38)

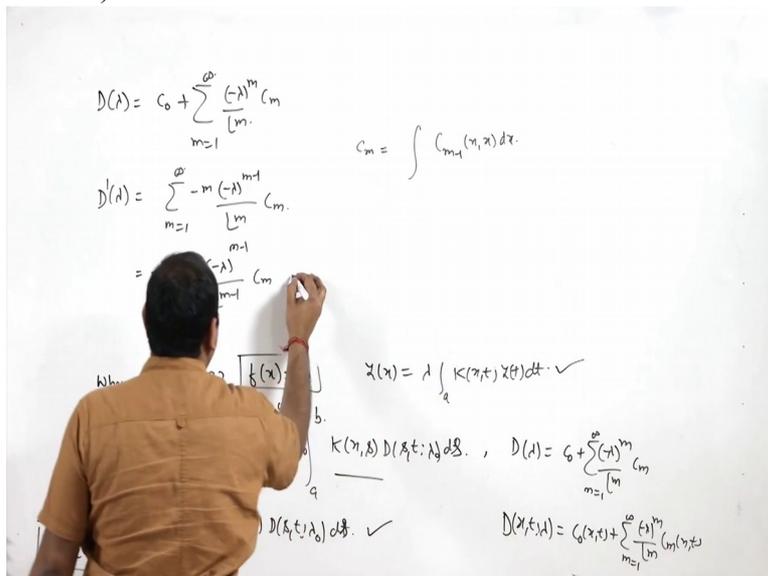

D dash lambda you will get minus m equal to 1 to infinity this part is simply vanished. So minus you will get, minus m minus lambda to power m minus 1 upon factorial m and c m. And if you simplify this you will get this as minus summation m equal to 1 to infinity this is m it will cancel out here minus lambda to power m minus 1 upon factorial m minus 1 small c m.

(Refer Slide Time 09:12)

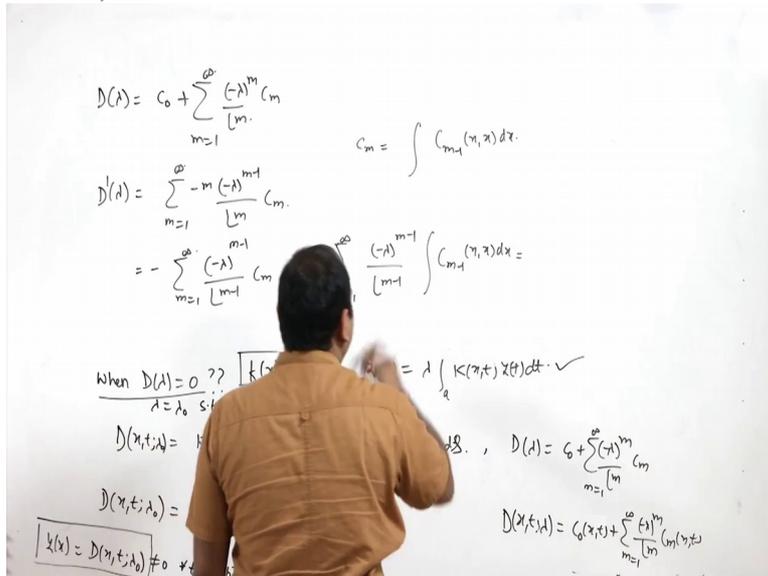

And we know that small c m is connected with capital C m minus 1 x comma x d x like this.
So

(Refer Slide Time 09:21)

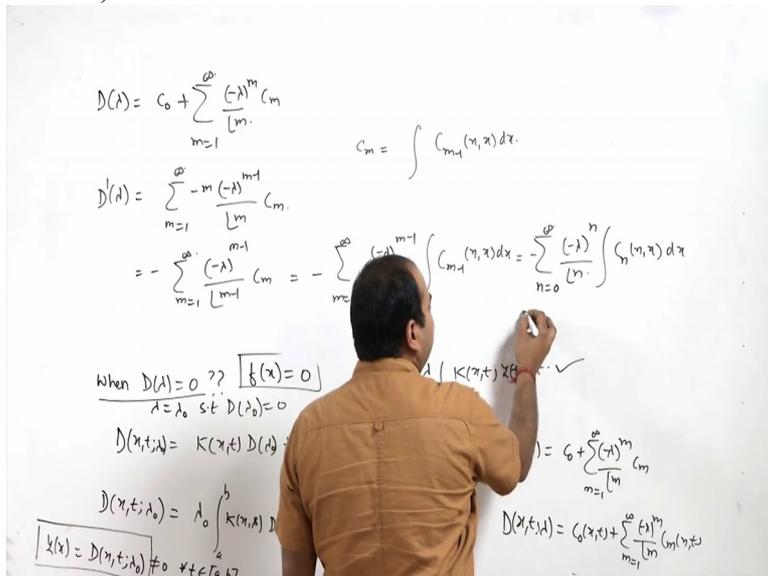

using this I can write it minus summation m equal to 1 to infinity minus lambda to power m minus 1 and upon factorial m minus 1, this c m I can write it as integral of c m minus 1 x comma x d of x. And if we simplify,

(Refer Slide Time 09:39)

if you replace this dummy variable m minus 1 by say some n , you can write it here that it is minus n equal to zero to infinity minus λ to power n upon factorial n and integral here c_{n-1} of x . Now this c infinite series is uniformly

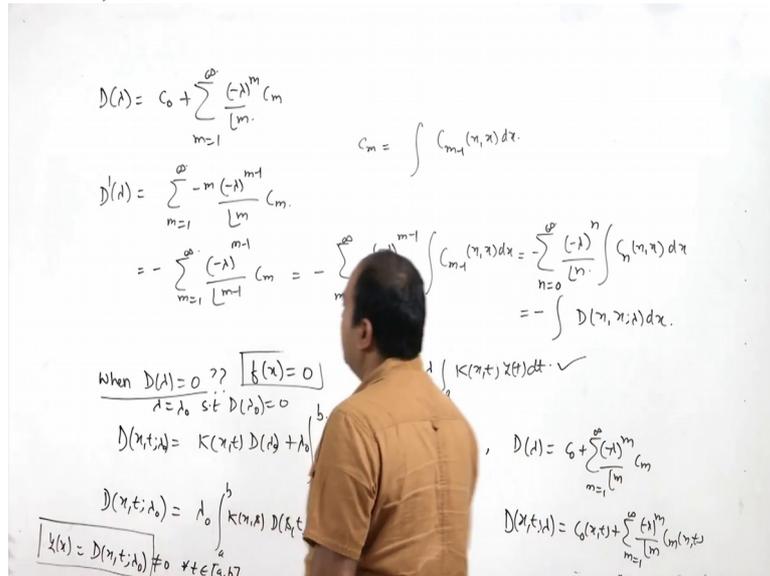

(Refer Slide Time 10:09)

convergent so we can interchange this integral sign and you can write this minus integral of, and if you take inside it is nothing but your D of x comma x lambda d of x .

So it means that your

(Refer Slide Time 10:25)

$D(\lambda)$ is related to $D(x, \lambda)$ in as this equation number 48. So it means that if we have

(Refer Slide Time 10:35)

Fredholm's Second Theorem

If $D(\lambda_0) = 0$ and $D(x, t; \lambda_0) \neq 0$, then for a proper choice of t say $t = t_0$, $y(x) = D(x, t_0; \lambda_0)$ is a continuous solution of

$$y(x) = \lambda_0 \int k(x, t)y(t)dt. \tag{47}$$

On differentiation of equation (37) and interchange the indices of the variable of integration, we obtain

$$D'(\lambda) = - \int D(x, x; \lambda) dx \tag{48}$$

Particularly, if λ_0 is a simple zero of $D(\lambda)$, then $D(\lambda_0) = 0$, $D'(\lambda_0) \neq 0$, and λ_0 is a simple pole of the resolvent kernel. Moreover, from (48), $D(x, t; \lambda) \neq 0$.

IIT ROORKEE
 NPTEL ONLINE CERTIFICATION COURSE
 39

λ_0 is a simple zero of $D(\lambda)$ in a way such that $D(\lambda_0) = 0$ but $D'(lambda_0) \neq 0$ or we can say that λ_0 is a simple zero of $D(\lambda)$ then this portion $D'(lambda_0) \neq 0$ so we can say that integral of $D(x, x; \lambda_0) dx$ is not equal to zero. So it means that this expression $D(x, x; \lambda_0)$ is not identically equal to zero. So we can say that when λ_0 is a simple zero of $D(\lambda)$ then this $y(x) = D(x, t_0; \lambda_0)$ is a solution of the homogenous Fredholm integral equation of this, $y(x) = \lambda_0 \int_a^b K(x, t)y(t) dt$.

So in this case,

(Refer Slide Time 11:27)

For this case if $D(\lambda) = 0$ and $D(x, t; \lambda) \neq 0$ then $D(x, t; \lambda)$ and $kD(x, t; \lambda)$ (where k is an arbitrary constant) will be the solution of the homogeneous equation (47). Now we discuss the general case when λ is a zero of an arbitrary multiplicity k , i.e., when

$$D(\lambda_0) = 0, \dots, D^{(r)}(\lambda_0) = 0, D^{(k)}(\lambda_0) \neq 0$$

where r stands for the derivative of the order $r, r = 1, \dots, k - 1$.

40

not only $D(x, t; \lambda)$ but any constant multiple of $D(x, t; \lambda)$ will be a solution of the homogeneous equation, homogeneous equation

(Refer Slide Time 11:37)

Fredholm's Second Theorem

If $D(\lambda_0) = 0$ and $D(x, t; \lambda_0) \neq 0$, then for a proper choice of t say $t = t_0$, $y(x) = D(x, t_0; \lambda_0)$ is a continuous solution of

$$y(x) = \lambda_0 \int k(x, t)y(t)dt. \quad (47)$$

On differentiation of equation (37) and interchange the indices of the variable of integration, we obtain

$$D'(\lambda) = - \int D(x, x; \lambda)dx \quad (48)$$

Particularly, if λ_0 is a simple zero of $D(\lambda)$, then $D(\lambda_0) = 0, D'(\lambda_0) \neq 0$, and λ_0 is a simple pole of the resolvent kernel. Moreover, from (48), $D(x, t; \lambda) \neq 0$.

39

this equation.

(Refer Slide Time 11:39)

For this case if $D(\lambda) = 0$ and $D(x, t; \lambda) \neq 0$ then $D(x, t; \lambda)$ and $kD(x, t; \lambda)$ (where k is an arbitrary constant) will be the solution of the homogeneous equation (47). Now we discuss the general case when λ is a zero of an arbitrary multiplicity k , i.e., when

$$D(\lambda_0) = 0, \dots, D^{(r)}(\lambda_0) = 0, \quad D^{(k)}(\lambda_0) \neq 0$$

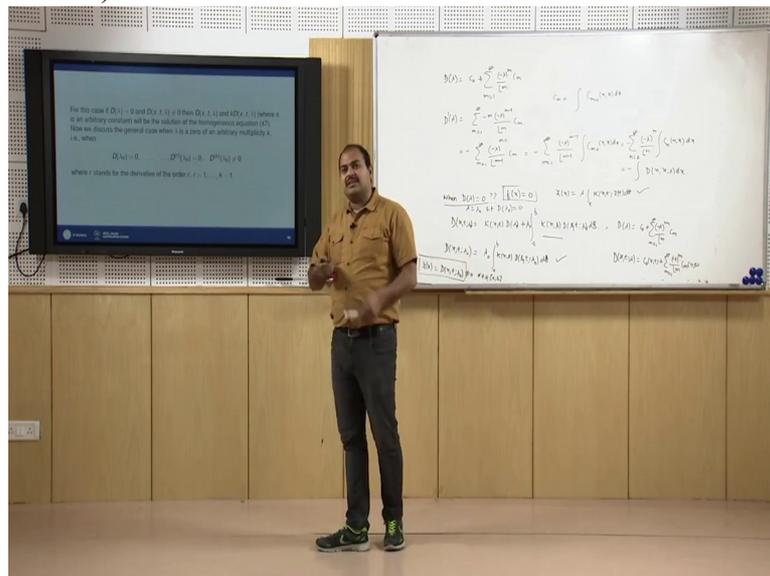

where r stands for the derivative of the order $r, r = 1, \dots, k - 1$.

40

Now we try to consider, we generalize the case here. So here we have discussed the case when lambda naught is a

(Refer Slide Time 11:48)

simple zero of $D(\lambda)$. Now what happens when λ_0 is a zero of $D(\lambda)$ with multiplicity say k . So it means that $D(\lambda_0)$ is

(Refer Slide Time 12:01)

For this case if $D(\lambda) = 0$ and $D(x, t; \lambda) \neq 0$ then $D(x, t; \lambda)$ and $kD(x, t; \lambda)$ (where k is an arbitrary constant) will be the solution of the homogeneous equation (47). Now we discuss the general case when λ is a zero of an arbitrary multiplicity k , i.e., when

$$D(\lambda_0) = 0, \dots, D^{(r)}(\lambda_0) = 0, \quad D^{(k)}(\lambda_0) \neq 0$$

where r stands for the derivative of the order $r, r = 1, \dots, k - 1$.

40

zero and up to $D^{k-1} \lambda_0$ is equal to zero but the k th derivative evaluated at λ_0 it is not equal to zero. So here we say that $\lambda = \lambda_0$, this is zero of $D(\lambda)$ of the order k , right and

(Refer Slide Time 12:21)

For this case we may define the n^{th} Fredholm minor as follows

$$D \begin{pmatrix} x_1 & x_2 & \dots & x_n \\ t_1 & t_2 & \dots & t_n \end{pmatrix} \Big| \lambda = K \begin{pmatrix} x_1 & x_2 & \dots & x_n \\ t_1 & t_2 & \dots & t_n \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \int \int K \begin{pmatrix} x_1 & x_2 & \dots & x_n & u_1 & \dots & u_p \\ t_1 & t_2 & \dots & t_n & u_1 & \dots & u_p \end{pmatrix} du_1 du_2 \dots du_p \quad (49)$$

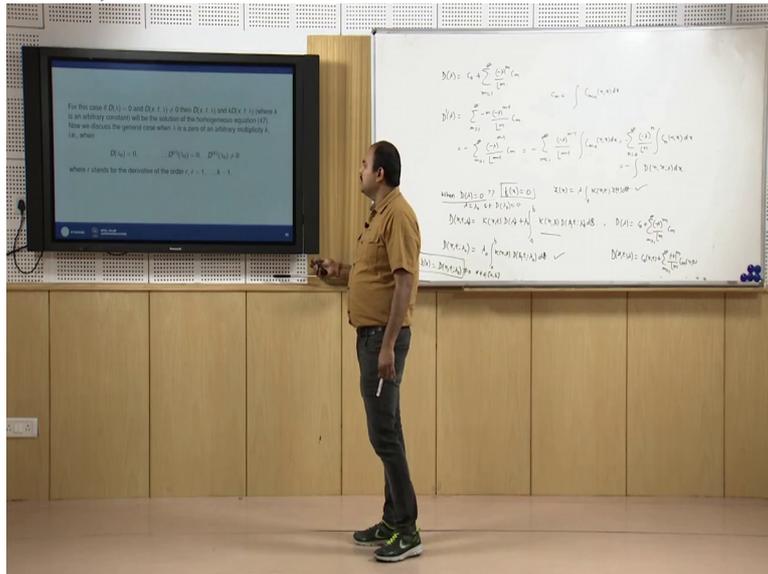

This series converges for all values of λ and is an entire function of λ . Differentiating the series of $D(\lambda)$ given in (37) n times and comparing it with (49), we obtain

41

here we try to find out the solution

(Refer Slide Time 12:24)

of our homogenous Fredholm equation given by 47.

So let me summarize here. When lambda naught is simple zero,

(Refer Slide Time 12:33)

Fredholm's Second Theorem

If $D(\lambda_0) = 0$ and $D(x, t; \lambda_0) \neq 0$, then for a proper choice of t say $t = t_0$, $y(x) = D(x, t_0; \lambda_0)$ is a continuous solution of

$$y(x) = \lambda_0 \int k(x, t)y(t)dt. \tag{47}$$

On differentiation of equation (37) and interchange the indices of the variable of integration, we obtain

$$D'(\lambda) = - \int D(x, x; \lambda) dx \tag{48}$$

Particularly, if λ_0 is a simple zero of $D(\lambda)$, then $D(\lambda_0) = 0$, $D'(\lambda_0) \neq 0$, and λ_0 is a simple pole of the resolvent kernel. Moreover, from (48), $D(x, t; \lambda) \neq 0$.

39

then $D(x, t; \lambda_0)$ is going to be a solution of this. Now we want to show that if λ_0 is a zero of $D(\lambda)$ with multiplicity k then in that case what should be extended or what should be the generalization of $D(x, t; \lambda_0)$.

(Refer Slide Time 12:50)

For this case if $D(\lambda) = 0$ and $D(x, t; \lambda) \neq 0$ then $D(x, t; \lambda)$ and $kD(x, t; \lambda)$ (where k is an arbitrary constant) will be the solution of the homogeneous equation (47). Now we discuss the general case when λ is a zero of an arbitrary multiplicity k , i.e., when

$$D(\lambda_0) = 0, \dots, D^{(r)}(\lambda_0) = 0, \quad D^{(k)}(\lambda_0) \neq 0$$

where r stands for the derivative of the order $r, r = 1, \dots, k - 1$.

40

So here for this we define a

(Refer Slide Time 12:53)

For this case we may define the n^{th} Fredholm minor as follows

$$D \begin{pmatrix} x_1 & x_2 & \dots & x_n \\ t_1 & t_2 & \dots & t_n \end{pmatrix} \Big| \lambda = K \begin{pmatrix} x_1 & x_2 & \dots & x_n \\ t_1 & t_2 & \dots & t_n \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \int \int K \begin{pmatrix} x_1 & x_2 & \dots & x_n & u_1 & \dots & u_p \\ t_1 & t_2 & \dots & t_n & u_1 & \dots & u_p \end{pmatrix} du_1 du_2 \dots du_p \quad (49)$$

This series converges for all values of λ and is an entire function of λ . Differentiating the series of $D(\lambda)$ given in (37) n times and comparing it with (49), we obtain

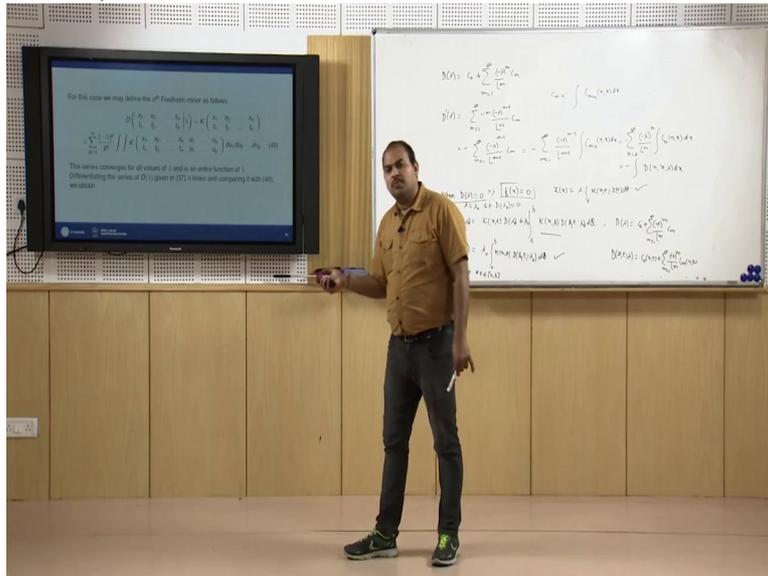

41

new term which is known as n^{th} row minor and it is defined as $d \times 1 \times 2 \times n \times t_1 \times t_2 \times t_n$ with respect to the given constant λ and it is given by $K \times 1 \times t_1 \times 2 \times t_2 \times \dots \times n \times t_n$ plus p equal to 1 to infinity minus λ to power p factorial p this is p integral $K \times 1 \times x_n \times t_1 \times \dots \times t_n \times u_1 \times \dots \times u_p \times u_1 \times \dots \times u_p \times du_1 \times du_2 \times \dots \times du_p$. So if we can define n^{th} Fredholm minor as defined as 49, then our claim is that this will be a kind of solution candidate for

(Refer Slide Time 13:36)

the homogenous integral equation. Now if you look at your equation number 49 in a clear manner, if we take

(Refer Slide Time 13:44)

For this case we may define the n^{th} Fredholm minor as follows

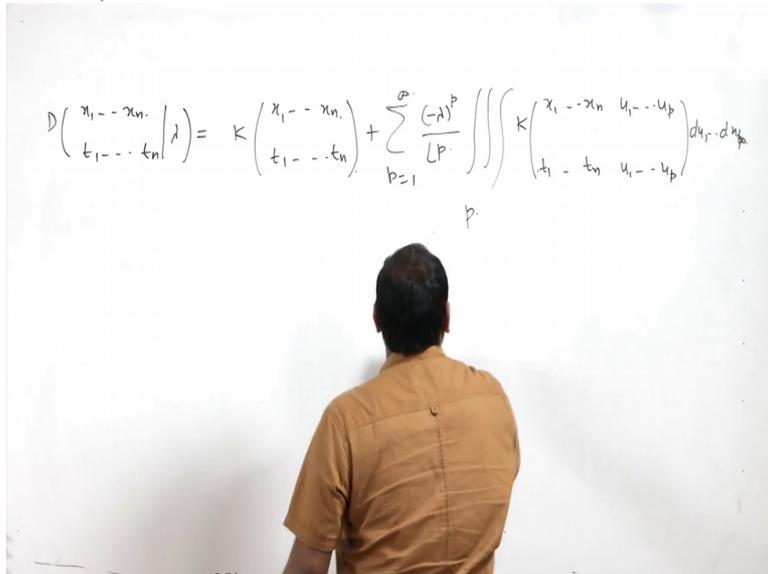

$$D \begin{pmatrix} x_1, x_2, \dots, x_n \\ t_1, t_2, \dots, t_n \end{pmatrix} \lambda = K \begin{pmatrix} x_1, x_2, \dots, x_n \\ t_1, t_2, \dots, t_n \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \int \int K \begin{pmatrix} x_1, x_2, \dots, x_n, u_1, \dots, u_p \\ t_1, t_2, \dots, t_n, u_1, \dots, u_p \end{pmatrix} du_1 du_2 \dots du_p \quad (49)$$

This series converges for all values of λ and is an entire function of λ .
Differentiating the series of $D(\lambda)$ given in (37) n times and comparing it with (49), we obtain

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 41

n equal to 1 so it means that we are considering the first Fredholm minor. So our claim is that this is nothing but your $D \times y \lambda$. If you look at equation number 49 and write down the expression for n equal to 1. So here if you look at this expression D of expression x_1 to x_n and t_1 to t_n with respect to λ it is given as $K \times 1$ to say $x_n t_1$ to t_n plus summation your p equal to 1 to infinity minus λ to power p upon factorial p and this is p -fold integral and here we have $K \times 1$ to $x_n t_1$ to t_n . And then u_1 to u_p and u_1 to u_p . And $d u_1$ to $d u_p$. I hope we already

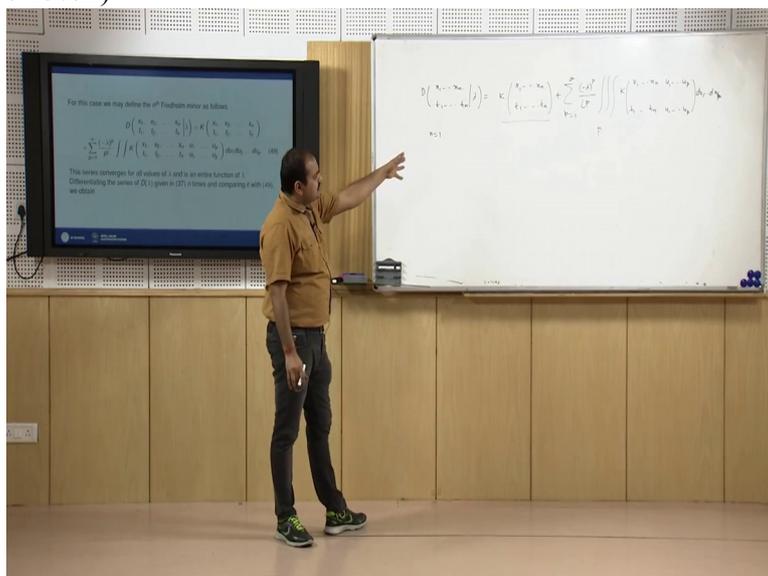

(Refer Slide Time 14:48)

know this symbol. So using this symbol we can say that your $D(x, y)$ written like this.

Now here if we take n equal to 1, then we try to see that

(Refer Slide Time 15:02)

this is reduced to your Fredholm minor that is $D(x, y, \lambda)$. So if you look at n equal to 1 then it is what, $D(x, t, 1)$ given as λ is equal to $K(x, t, 1)$. Now if you look at the notation here, this is what, this is, notation is determinant here, $x, 1$, so this, we already know this is $K(x, t, 1)$ $K(x, t, 2)$ and so on $K(x, t, n)$ and so on. So here it is $K(x, n, t, 1)$ and $K(x, n, t, n)$. So here using this notation you can say that $K(x, t, 1)$ is nothing but $K(x, t)$. So let me write it first and we will simplify this. $t, 1$ plus summation p equal to 1 to infinity minus λ to power p upon factorial p and this is p integral, and this is $K(x, t)$ and this is $t, 1$ and then $u, 1$ to u, p and $u, 1$ to u, p and $du, 1$ to du, p . So if you simplify

(Refer Slide Time 16:20)

$$D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} \lambda = K \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \iiint K \begin{pmatrix} x_1 & \dots & x_n & u_1 & \dots & u_p \\ t_1 & \dots & t_n & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$n=1 \quad \left| \begin{matrix} K(x_1, t_1) & K(x_1, t_2) & \dots & K(x_1, t_n) \\ t'(x_1, t_1) & \dots & \dots & K(x_1, t_n) \end{matrix} \right|$$

$$D \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} \lambda = K \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \iiint K \begin{pmatrix} x_1 & u_1 & \dots & u_p \\ t_1 & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

this is what, this I can write it, let me write this as $x_1 t_1 \lambda$ this is what $K \times x_1 t_1$ using this notation it is nothing but 1×1 that is $K \times x_1 t_1$ plus summation p equal to 1 to infinity minus λ to power p upon factorial p . And if you simplify this, you can say that this is nothing but c_p of x of $x_1 t_1$.

So, and this I can write it as $c_{naught} \times x_1 t_1$. So it means that, that this is the n th, Fredholm minor is a generalization

(Refer Slide Time 17:03)

$$D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} \lambda = K \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \iiint K \begin{pmatrix} x_1 & \dots & x_n & u_1 & \dots & u_p \\ t_1 & \dots & t_n & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$n=1 \quad \left| \begin{matrix} K(x_1, t_1) & K(x_1, t_2) & \dots & K(x_1, t_n) \\ t'(x_1, t_1) & \dots & \dots & K(x_1, t_n) \end{matrix} \right|$$

$$D \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} \lambda = K \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \iiint K \begin{pmatrix} x_1 & u_1 & \dots & u_p \\ t_1 & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$D(x_1, t_1; \lambda) = c_0(x_1, t_1) + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} c_p(x_1, t_1)$$

of this Fredholm minor for n equal to 1 . So I can say if we want to write it, this is equal to this, Ok. So it means that the n th minor is a generalization of Fredholm minor. Or you can

further simplify this as follows. If you want to write this, you can write this as $D_{p \times n}(\lambda)$ or this is written as $D_{p \times n}(\lambda)$, let me write it here. So I can say that

(Refer Slide Time 17:46)

$$D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} (\lambda) = K \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \iiint K \begin{pmatrix} x_1 & \dots & x_n & u_1 & \dots & u_p \\ t_1 & \dots & t_n & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$n=1 \quad \Rightarrow D_n(x, y; \lambda) = D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} (\lambda)$$

$$D \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} = K \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \iiint K \begin{pmatrix} x_1 & u_1 & \dots & u_p \\ t_1 & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$D(x_1, t_1; \lambda) = K(x_1, t_1) + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} B_p(x_1, t_1)$$

this is $D_{n \times n}(\lambda)$. It is $D_{n \times 1}$ to x_1 to x_n t_1 to t_n λ . Let me write it here.

This I can write it here as $B_n(x, y)$ plus summation p equal to 1 to infinity, you can write it B_p . This x, y , Ok x, y , right. So here $B_n(x, y)$ is defined

(Refer Slide Time 18:09)

$$D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} (\lambda) = K \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \iiint K \begin{pmatrix} x_1 & \dots & x_n & u_1 & \dots & u_p \\ t_1 & \dots & t_n & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

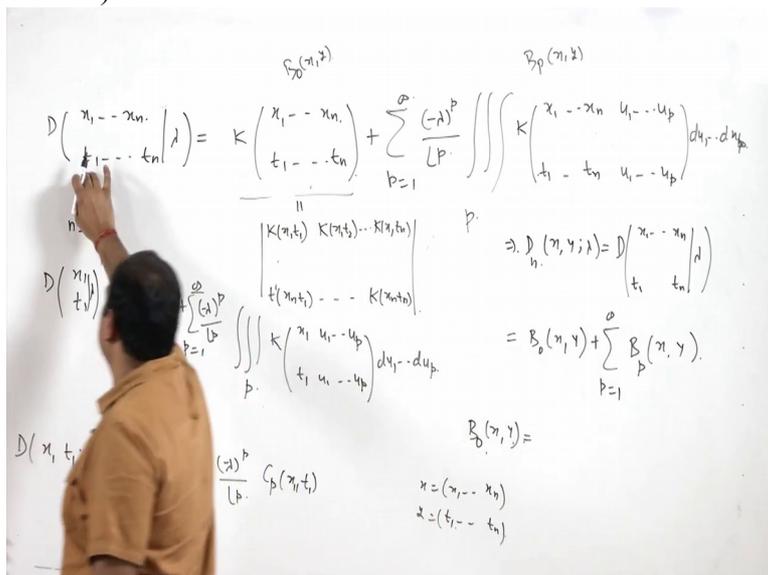

$$n=1 \quad \Rightarrow D_n(x, y; \lambda) = D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} (\lambda)$$

$$D \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} = K \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \iiint K \begin{pmatrix} x_1 & u_1 & \dots & u_p \\ t_1 & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$D(x_1, t_1; \lambda) = K(x_1, t_1) + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} B_p(x_1, t_1)$$

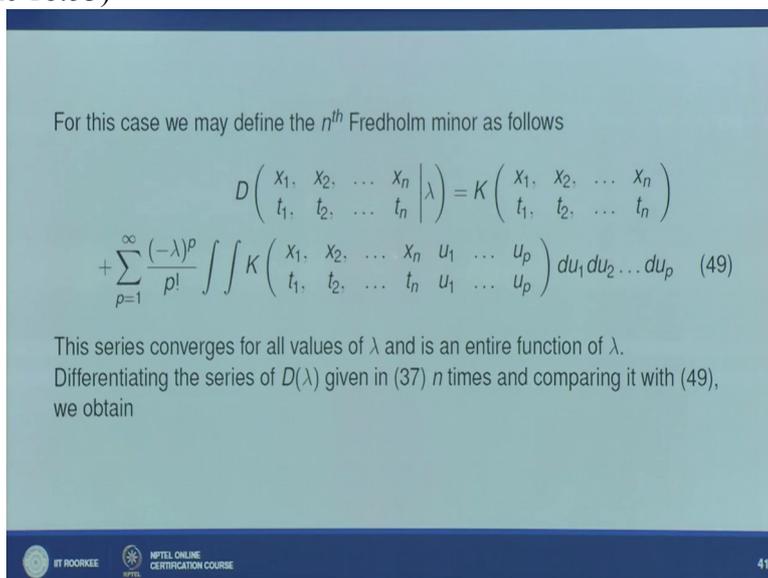

as what, $B_n(x, y)$ is given by this thing. So you can say that x is nothing but your x_1 to x_n and y is your t_1 to t_n . And $B_n(x, y)$ is defined as this, so this you can call it $B_n(x, y)$ and this you can call it B_p of x, y . So if you define it like this, this is nothing but

(Refer Slide Time 18:34)

generalization of the first Fredholm minor, Ok. So we try to show that this is going to give you the solution of the homogenous Fredholm equation. So here let us relate this nth Fredholm minor

(Refer Slide Time 18:53)

with the derivative of Fredholm determinant that is $D \lambda$. So if we look at, we have already this kind of relation given as

(Refer Slide Time 19:02)

Fredholm's Second Theorem

If $D(\lambda_0) = 0$ and $D(x, t; \lambda_0) \neq 0$, then for a proper choice of t say $t = t_0$, $y(x) = D(x, t_0; \lambda_0)$ is a continuous solution of

$$y(x) = \lambda_0 \int k(x, t)y(t)dt. \quad (47)$$

On differentiation of equation (37) and interchange the indices of the variable of integration, we obtain

$$D'(\lambda) = - \int D(x, x; \lambda) dx \quad (48)$$

Particularly, if λ_0 is a simple zero of $D(\lambda)$, then $D(\lambda_0) = 0$, $D'(\lambda_0) \neq 0$, and λ_0 is a simple pole of the resolvent kernel. Moreover, from (48), $D(x, t; \lambda) \neq 0$.

BY ROORKEE NPTEL ONLINE CERTIFICATION COURSE 39

48 so when n equal to 1, we have a relation that D dash λ is equal to minus D x comma x lambda. Now in the case when n is more than 1, then do we have any relation of this 48 kind? Then here we will not do it but when you differentiate D of λ that is Fredholm determinant with n th times you will see that it is coming to be minus 1 to power n ,

(Refer Slide Time 19:31)

$$\frac{d^n D(\lambda)}{d\lambda^n} = (-1)^n \int \dots \int D \left(\begin{matrix} x_1, & x_2, & \dots & x_n \\ x_1, & x_2, & \dots & x_n \end{matrix} \middle| \lambda \right) dx_1 dx_2 \dots dx_n. \quad (50)$$

Thus we conclude that if λ_0 is a zero of multiplicity k of the function $D(\lambda)$, the

$$D \left(\begin{matrix} x_1, & x_2, & \dots & x_k \\ t_1, & t_2, & \dots & t_k \end{matrix} \middle| \lambda_0 \right) \neq 0. \quad (51)$$

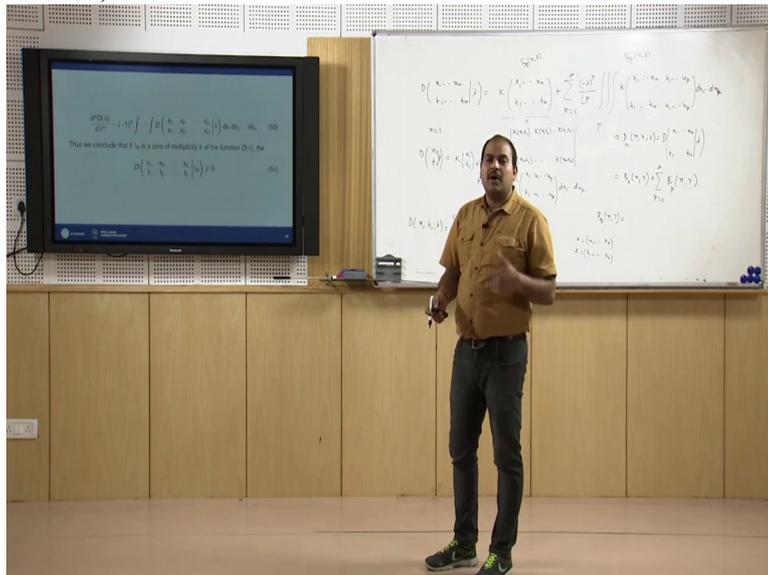

BY ROORKEE NPTEL ONLINE CERTIFICATION COURSE 42

this is n times n -fold integral D of x_1 to x_n , x_1 to x_n lambda $d x_1$ to $d x_n$.

So it means that we do have the similar kind of relation as we have seen that D dash λ is equal to minus of integral D x comma x lambda. Similarly this equation number 55 shows that when n is more than 1, then also we have a similar kind of relation. And we say that if λ_0 is a zero of multiplicity k of the function $D(\lambda)$ then means what that D K

lambda naught is non zero. So it means that with the help of this equation number 50, we can say that b kth minus kth Fredholm minor that is $d \times 1$ to $x, k, x, 1$ to $x, k, t, 1$ to t, k , this lambda naught is not equal to zero. This means that if this is a kind of relation between the zeroes of $D \lambda$ and the solution candidate, that is this. So it means that if lambda naught is a zero of multiplicity of k of this function $D \lambda$ then k th minor is not equal to zero. But we may have that there is a k minus 1th minor

(Refer Slide Time 20:49)

or say, k minus 2th minor may also not be equal to zero. So it means that we can always choose a number q which is less than k such that the q th minor of Fredholm minor, the k th minor of $D \lambda$ is not equal to zero, Ok. So with the help of that we can define the notion, that is index, Ok. So we will define that later on. But before that we will try to see that this n th minor, n th Fredholm minor will satisfy similar kind of integral equation. So if we know that this $D \times y \lambda$ is equal to K of $x, t, D \lambda$, I think I have to write t here, that $D \times t \lambda$ is equal to $K \times t$ plus $D \lambda$ plus λa to b, K of x of s, D of $s, t \lambda, d$ of s . So it means that

(Refer Slide Time 21:55)

$$D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} \lambda = K \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \int \dots \int K \begin{pmatrix} x_1 & \dots & x_n & u_1 & \dots & u_p \\ t_1 & \dots & t_n & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$D \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} = K \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \int \dots \int K \begin{pmatrix} x_1 & u_1 & \dots & u_p \\ t_1 & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$D(x, t; \lambda) = K(x, t) D(\lambda) + \lambda \int_a^b K(x, \beta) D(\beta; \lambda) d\beta$$

we already know that this Fredholm minor satisfies this relation, we want to know the generalization that is n th minor of, nth Fredholm minor will also satisfy similar kind of equation or not, so for that what try to do here,we look at the similar kind of expression.

So here if you have

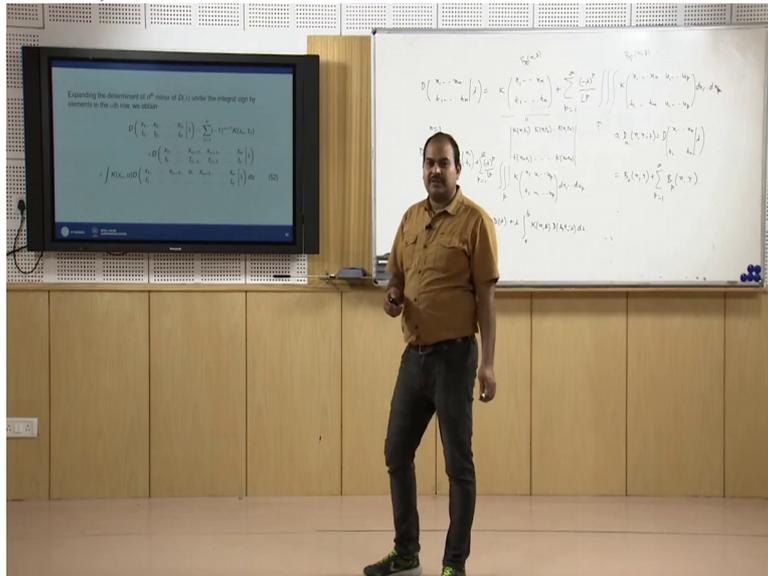

(Refer Slide Time 22:15)

Expanding the determinant of n^{th} minor of $D(\lambda)$ under the integral sign by elements in the α th row, we obtain

$$D \begin{pmatrix} x_1 & x_2 & \dots & x_n \\ t_1 & t_2 & \dots & t_n \end{pmatrix} \lambda = \sum_{\beta=1}^n (-1)^{\alpha+\beta} K(x_\alpha, t_\beta) \times D \begin{pmatrix} x_1 & \dots & x_{\alpha-1} & x_{\alpha+1} & \dots & x_n \\ t_1 & \dots & t_{\beta-1} & t_{\beta+1} & \dots & t_n \end{pmatrix} \lambda + \int K(x_\alpha, u) D \begin{pmatrix} x_1 & \dots & x_{\alpha-1} & u & x_{\alpha+1} & \dots & x_n \\ t_1 & \dots & \dots & \dots & \dots & \dots & t_n \end{pmatrix} \lambda du \quad (52)$$

this expression nth minor of, nth Fredholm minor of D lambda and if we expand this determinant with the help of say, along the alpha th row and when we simplify we can get this kind of relation 52. This simplification involves a lot of say, calculation thing.

(Refer Slide Time 22:37)

So I am not presenting here the calculation part. Only thing I am giving here is that this D , this n th minor of D lambda will satisfy this integral equation 52 and this when you are doing the expansion of your determinant

(Refer Slide Time 22:53)

Expanding the determinant of n^{th} minor of $D(\lambda)$ under the integral sign by elements in the α th row, we obtain

$$D \left(\begin{array}{c} x_1, x_2, \dots, x_n \\ t_1, t_2, \dots, t_n \end{array} \middle| \lambda \right) = \sum_{\beta=1}^n (-1)^{\alpha+\beta} K(x_\alpha, t_\beta) \times D \left(\begin{array}{c} x_1, \dots, x_{\alpha-1}, x_{\alpha+1}, \dots, x_n \\ t_1, \dots, t_{\beta-1}, t_{\beta+1}, \dots, t_n \end{array} \middle| \lambda \right) + \int K(x_\alpha, u) D \left(\begin{array}{c} x_1, \dots, x_{\alpha-1}, u, x_{\alpha+1}, \dots, x_n \\ t_1, \dots, \dots, \dots, \dots, t_n \end{array} \middle| \lambda \right) du \quad (52)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 43

along the alpha th row. If you do the same expression with the beta th

(Refer Slide Time 22:58)

Similarly, expanding the determinant under the integral sign by elements in the β th column, we obtain

$$D \begin{pmatrix} x_1, x_2, \dots, x_n \\ t_1, t_2, \dots, t_n \end{pmatrix} \lambda = \sum_{\alpha=1}^n (-1)^{\alpha+\beta} K(x_\alpha, t_\beta) \times D \begin{pmatrix} x_1, \dots, x_{\alpha-1}, x_{\alpha+1}, \dots, x_n \\ t_1, \dots, t_{\beta-1}, t_{\beta+1}, \dots, t_n \end{pmatrix} + \int K(u, t_\beta) D \begin{pmatrix} x_1, \dots, x_n \\ t_1, \dots, t_{\beta-1}, u, t_{\beta+1}, \dots, t_n \end{pmatrix} du \quad (53)$$

Note that the relations (52) and (53) hold for all values of λ .

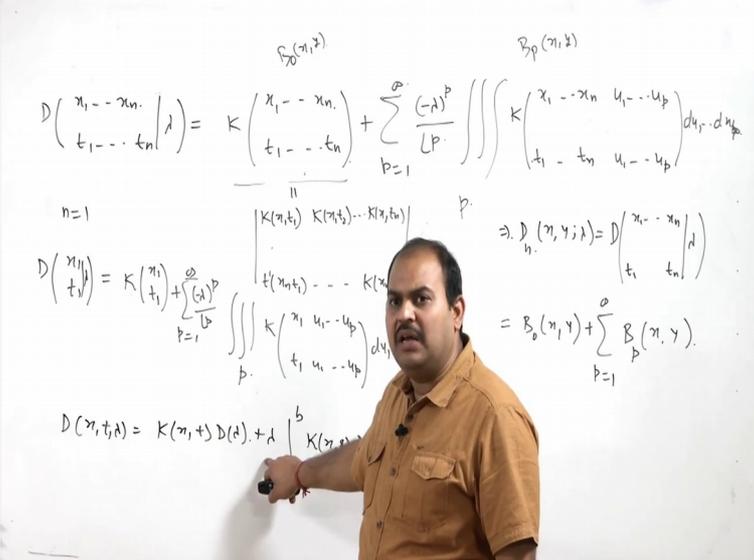

44

column, then we also have the similar kind of integral equation. So here if you look at this equation number 52 and the equation number 53 is kind of integral equation similar to the integral equation satisfied by

(Refer Slide Time 23:15)

$$D \begin{pmatrix} x_1, \dots, x_n \\ t_1, \dots, t_n \end{pmatrix} \lambda = \sum_{\alpha=1}^n (-1)^{\alpha+\beta} K(x_\alpha, t_\beta) \dots + \int_a^b K(x_1, u) D \begin{pmatrix} x_1 \\ t_1, u \end{pmatrix} du$$

$$n=1 \quad D \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} \lambda = K(x_1, t_1) \lambda + \int_a^b K(x_1, u) D \begin{pmatrix} x_1 \\ t_1, u \end{pmatrix} du$$

$$D(x_1, t_1, \lambda) = K(x_1, t_1) D(x_1) + \lambda \int_a^b K(x_1, u) D(x_1, u) du$$

$D \times t \lambda$. So we try to see that this equation number

(Refer Slide Time 23:19)

Similarly, expanding the determinant under the integral sign by elements in the β th column, we obtain

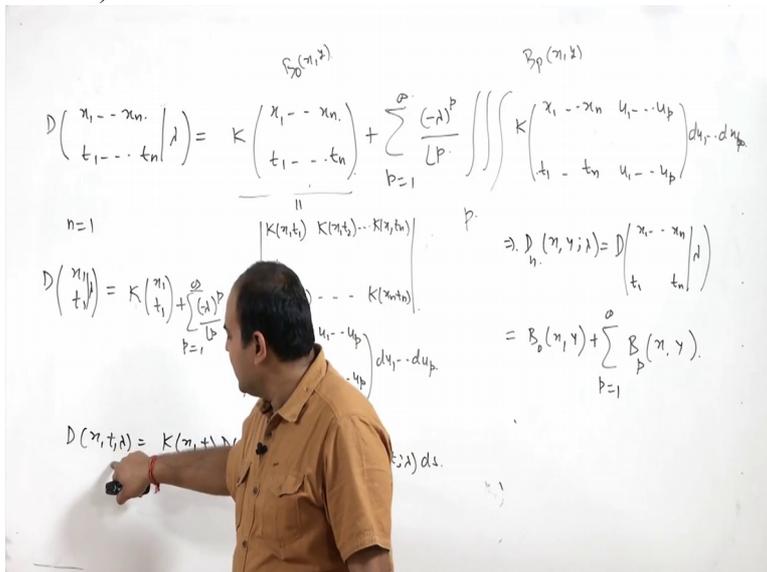

$$D \begin{pmatrix} x_1 & x_2 & \dots & x_n \\ t_1 & t_2 & \dots & t_n \end{pmatrix} \lambda = \sum_{\alpha=1}^n (-1)^{\alpha+\beta} K(x_\alpha, t_\beta) \times D \begin{pmatrix} x_1 & \dots & x_{\alpha-1} & x_{\alpha+1} & \dots & x_n \\ t_1 & \dots & t_{\beta-1} & t_{\beta+1} & \dots & t_n \end{pmatrix} + \int K(u, t_\beta) D \begin{pmatrix} x_1 & \dots & \dots & \dots & \dots & x_n \\ t_1 & \dots & t_{\beta-1} & u & t_{\beta+1} & \dots & t_n \end{pmatrix} du \quad (53)$$

Note that the relations (52) and (53) hold for all values of λ .

52 and 53 will give you, say some method to find out the solution when your D lambda is not equal to, D lambda is equal to zero. So here as we know that this expression, then D x t lambda

(Refer Slide Time 23:35)

$$D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} \lambda = \underbrace{K(x_1, t_\beta) \dots K(x_n, t_\beta)}_{\Pi} + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \int \dots \int K \begin{pmatrix} x_1 & \dots & x_n & u_1 & \dots & u_p \\ t_1 & \dots & t_n & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$n=1 \quad \underbrace{K(x_1, t_1) \dots K(x_1, t_1)}_{\Pi} \quad \Rightarrow D(x_1, y; \lambda) = D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} \lambda$$

$$D \begin{pmatrix} x_1 \\ t_1 \end{pmatrix} \lambda = K(x_1, t_1) \lambda + \sum_{p=1}^{\infty} \frac{(-\lambda)^p}{p!} \int \dots \int K \begin{pmatrix} x_1 & \dots & x_n & u_1 & \dots & u_p \\ t_1 & \dots & t_n & u_1 & \dots & u_p \end{pmatrix} du_1 \dots du_p$$

$$D(x_1, t_1, \lambda) = K(x_1, t_1) \lambda + \sum_{p=1}^{\infty} B_p(x_1, y) \lambda^p$$

is a, basically you can find out this expression is valid for all values of lambda. In the same way you can say that your 52 and 53,

(Refer Slide Time 23:44)

Similarly, expanding the determinant under the integral sign by elements in the β th column, we obtain

$$D \begin{pmatrix} x_1 & x_2 & \dots & x_n \\ t_1 & t_2 & \dots & t_n \end{pmatrix} \lambda = \sum_{\alpha=1}^n (-1)^{\alpha+\beta} K(x_\alpha, t_\beta) \times D \begin{pmatrix} x_1 & \dots & x_{\alpha-1} & x_{\alpha+1} & \dots & x_n \\ t_1 & \dots & t_{\beta-1} & t_{\beta+1} & \dots & t_n \end{pmatrix} \lambda + \int K(u, t_\beta) D \begin{pmatrix} x_1 & \dots & \dots & \dots & \dots & x_n \\ t_1 & \dots & t_{\beta-1} & u & t_{\beta+1} & \dots & t_n \end{pmatrix} \lambda du \quad (53)$$

Note that the relations (52) and (53) hold for all values of λ .

44

these two expression also hold for all values of lambda. So not only those values for which D lambda is not equal to zero. It is valid for all values of lambda.

So with the help of 52 and 53 we try to now discuss the case when D lambda naught, lambda naught is zero of D lambda. So now we can say that 52 and 53, we tried to get this, that we can find the solution

(Refer Slide Time 24:14)

From (52), we can find the solution of the homogeneous equation (47) for the special case when $\lambda = \lambda_0$ is an eigenvalue. Let us suppose that $\lambda = \lambda_0$ is a zero of multiplicity k of the function $D(\lambda)$. Then the minor D_k (k^{th} order minor of $D(\lambda)$) does not identically vanish even the minors D_1, D_2, \dots, D_{k-1} may not identically vanish. Let D_r be the first minor in the sequence D_1, D_2, \dots, D_{k-1} that does not identically vanish. The number r lies between 1 and k and is the index of the eigenvalue λ_0 . Moreover $D_{r-1} = 0$. But then (52) implies that

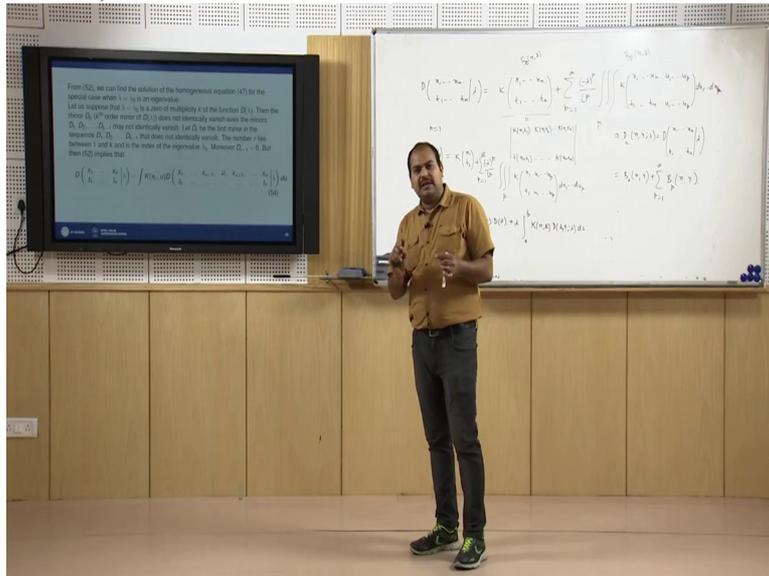

$$D \begin{pmatrix} x_1 & \dots & x_n \\ t_1 & \dots & t_n \end{pmatrix} \lambda = \int K(x_\alpha, u) D \begin{pmatrix} x_1 & \dots & x_{\alpha-1} & u & x_{\alpha+1} & \dots & x_n \\ t_1 & \dots & \dots & \dots & \dots & \dots & t_n \end{pmatrix} \lambda du. \quad (54)$$

45

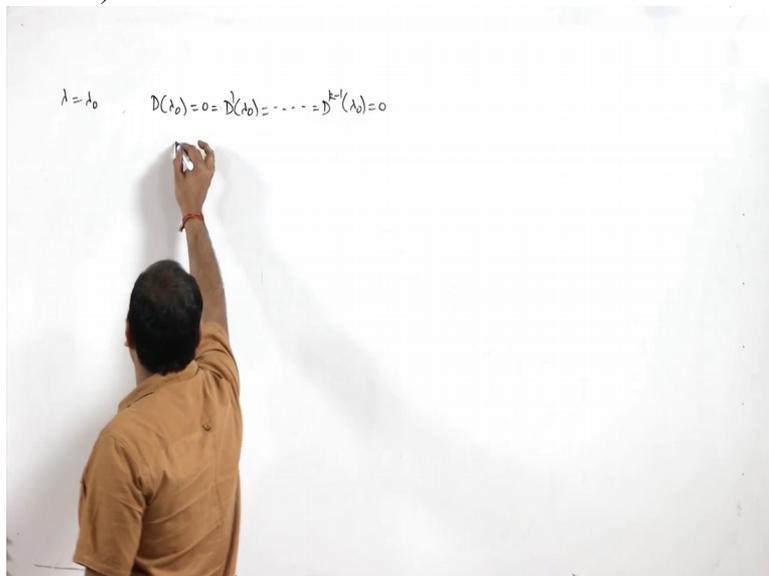

of the homogenous equation for the special case when lambda equal to lambda naught is an eigenvalue. So let us assume that this lambda equal to lambda naught is a zero of multiplicity k of the function D lambda. So it means that D lambda, D dash lambda

(Refer Slide Time 24:30)

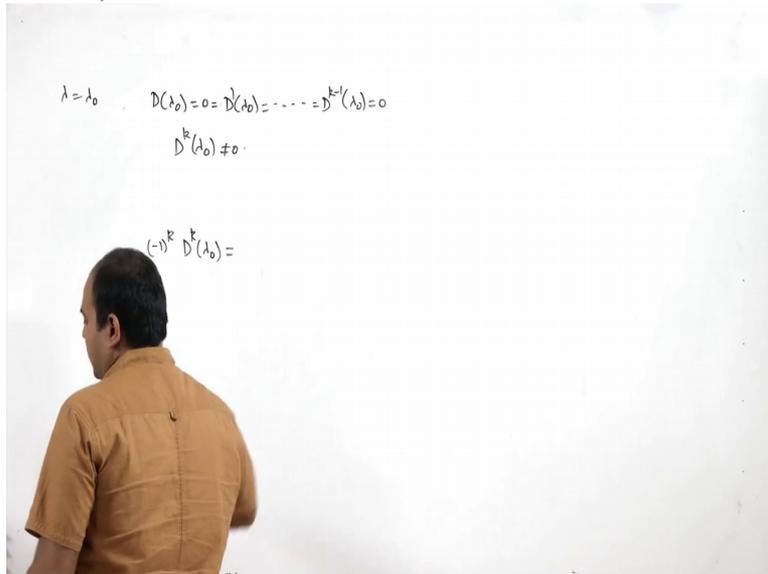

up to $D^{k-1} \lambda_0$ is equal to zero, let me write it here so that, so here we know that λ_0 is a zero of multiplicity k . So it means that $D \lambda_0 = 0$ and $D^2 \lambda_0 = 0$ and so on up to $D^{k-1} \lambda_0 = 0$. And your

(Refer Slide Time 24:58)

$D^k \lambda_0 \neq 0$, Ok.
Now we know that, from this relation that is $D^k \lambda_0 \neq 0$

(Refer Slide Time 25:12)

is equal to your relation, if you remember

(Refer Slide Time 25:15)

Similarly, expanding the determinant under the integral sign by elements in the β th column, we obtain

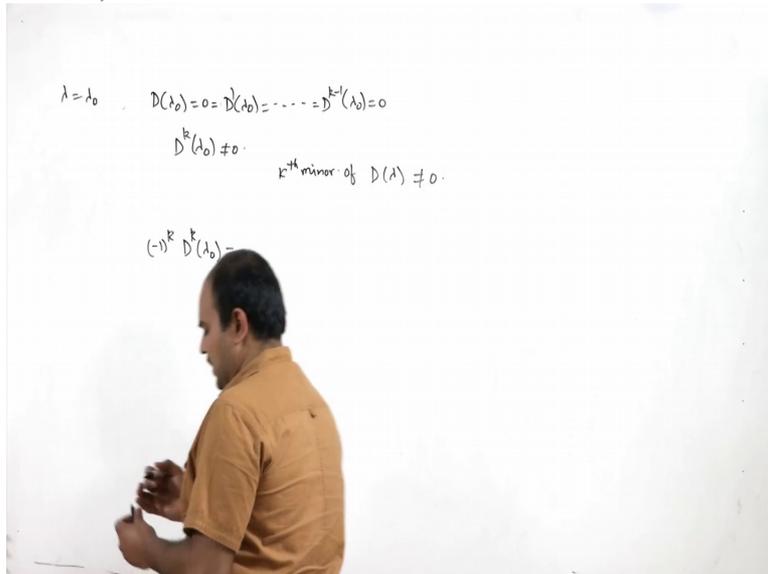

$$\begin{aligned}
 D \left(\begin{array}{c} x_1, x_2, \dots, x_n \\ t_1, t_2, \dots, t_n \end{array} \middle| \lambda \right) &= \sum_{\alpha=1}^n (-1)^{\alpha+\beta} K(x_\alpha, t_\beta) \\
 &\times D \left(\begin{array}{c} x_1, \dots, x_{\alpha-1}, x_{\alpha+1}, \dots, x_n \\ t_1, \dots, t_{\beta-1}, t_{\beta+1}, \dots, t_n \end{array} \middle| \lambda \right) \\
 &+ \int K(u, t_\beta) D \left(\begin{array}{c} x_1, \dots, \dots, \dots, \dots, x_n \\ t_1, \dots, t_{\beta-1}, u, t_{\beta+1}, \dots, t_n \end{array} \middle| \lambda \right) du \quad (53)
 \end{aligned}$$

Note that the relations (52) and (53) hold for all values of λ .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 44

equation number 50 here, this relation that D^k , d and D lambda, differentiation of D lambda with with respect to lambda nth time , this 50. So this means that if D^k lambda is non zero, the corresponding kth minor is also non-zero, right? So it means that, this implies that the k th minor of D lambda is also not equal to zero. But

(Refer Slide Time 25:50)

it may happen that this K minus 1th minor or say anything lesser than that is also equal to, is also not equal to zero. So what we try to do here, we try to find out say,

(Refer Slide Time 26:04)

For this case if $D(\lambda) = 0$ and $D(x, t; \lambda) \neq 0$ then $D(x, t; \lambda)$ and $kD(x, t; \lambda)$ (where k is an arbitrary constant) will be the solution of the homogeneous equation (47). Now we discuss the general case when λ is a zero of an arbitrary multiplicity k , i.e., when

$$D(\lambda_0) = 0, \dots, D^{(r)}(\lambda_0) = 0, D^{(k)}(\lambda_0) \neq 0$$

where r stands for the derivative of the order $r, r = 1, \dots, k - 1$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 40

the value of r for which, just a minute, yeah, here, here

(Refer Slide Time 26:14)

From (52), we can find the solution of the homogeneous equation (47) for the special case when $\lambda = \lambda_0$ is an eigenvalue.

Let us suppose that $\lambda = \lambda_0$ is a zero of multiplicity k of the function $D(\lambda)$. Then the minor D_k (k^{th} order minor of $D(\lambda)$) does not identically vanish even the minors D_1, D_2, \dots, D_{k-1} may not identically vanish. Let D_r be the first minor in the sequence D_1, D_2, \dots, D_{k-1} that does not identically vanish. The number r lies between 1 and k and is the index of the eigenvalue λ_0 . Moreover $D_{r-1} = 0$. But then (52) implies that

$$D \begin{pmatrix} x_1, \dots, x_n \\ t_1, \dots, t_n \end{pmatrix} \Big| \lambda = \int K(x_\alpha, u) D \begin{pmatrix} x_1, \dots, x_{\alpha-1}, u, x_{\alpha+1}, \dots, x_n \\ t_1, \dots, \dots, \dots, \dots, t_n \end{pmatrix} \Big| \lambda du. \quad (54)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 45

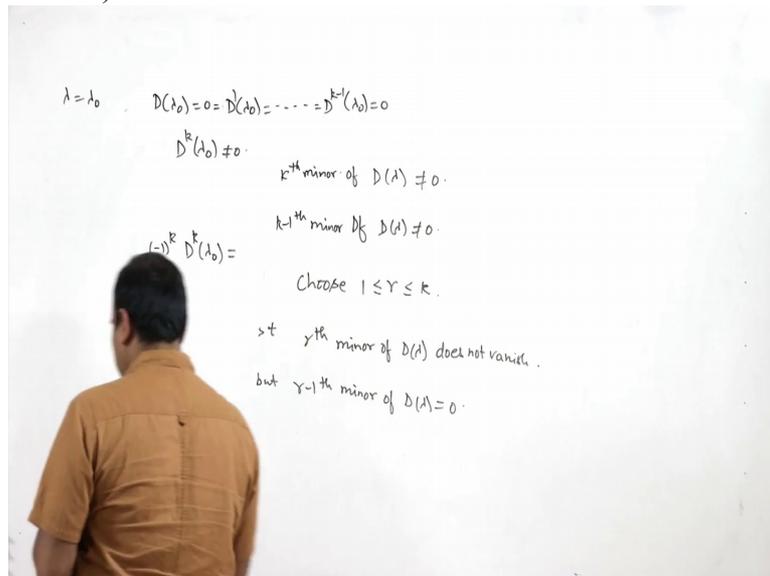

we already know that lambda equal to lambda naught is a zero of multiplicity k of the function D lambda then the minor D k does not identically vanish, even the minus D 1 to D k minus may not identically vanish. So let us find out, say r such that D r be the first minor in the sequence that does not identically vanish. So it means that, that before that it means that D r minus 1 is equal to zero. So that means that kth minor is not vanishing. It may happen that this k minus 1th member minor will also not vanish. So what we can

(Refer Slide Time 27:05)

$\lambda = \lambda_0 \quad D(\lambda_0) = 0 = D'(\lambda_0) = \dots = D^{(k-1)}(\lambda_0) = 0$
 $D^{(k)}(\lambda_0) \neq 0$
 k^{th} minor of $D(\lambda) \neq 0$
 $(-1)^r D^{(k)}(\lambda)$
 $(r-1)^{\text{th}}$ minor of $D(\lambda) = 0$

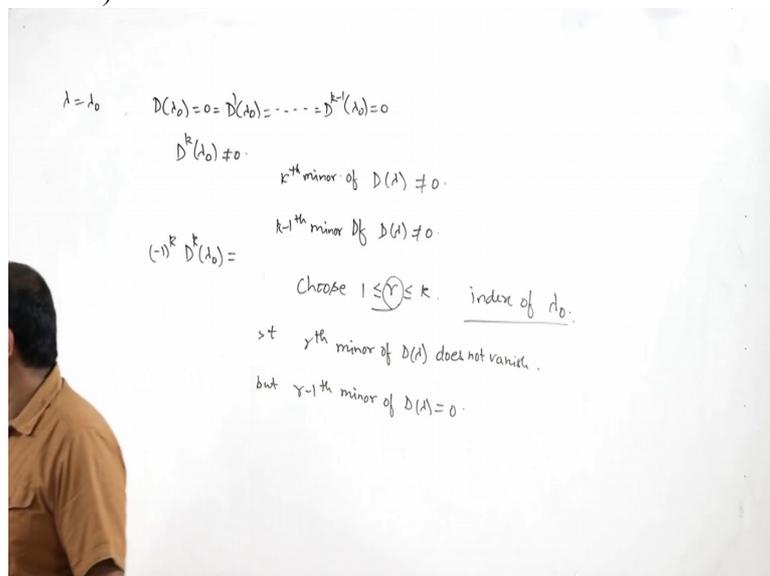

choose, say r which is between 1 to say, this k such that rth minor of D lambda does not vanish. But r minus 1th minor of D lambda is equal to zero. Is that Ok?

(Refer Slide Time 27:33)

So it means that if we do this, such a number, this r , such a number is called index of lambda naught. So if r is the index of lambda naught that is r th minor of D lambda does not vanish but r minus 1th minor of D lambda is equal to zero, in fact any minor whose order is less than r is going to vanish.

(Refer Slide Time 28:04)

In that case equation number 52 reduces to this integral

(Refer Slide Time 28:08)

From (52), we can find the solution of the homogeneous equation (47) for the special case when $\lambda = \lambda_0$ is an eigenvalue. Let us suppose that $\lambda = \lambda_0$ is a zero of multiplicity k of the function $D(\lambda)$. Then the minor D_k (k^{th} order minor of $D(\lambda)$) does not identically vanish even the minors D_1, D_2, \dots, D_{k-1} may not identically vanish. Let D_r be the first minor in the sequence D_1, D_2, \dots, D_{k-1} that does not identically vanish. The number r lies between 1 and k and is the index of the eigenvalue λ_0 . Moreover $D_{r-1} = 0$. But then (52) implies that

$$D \begin{pmatrix} x_1, & \dots & x_r \\ t_1, & \dots & t_r \end{pmatrix} \Big| \lambda = \int K(x_\alpha, u) D \begin{pmatrix} x_1, & \dots & x_{\alpha-1}, & u, & x_{\alpha+1}, & \dots & x_r \\ t_1, & \dots & \dots & \dots & \dots & \dots & t_r \end{pmatrix} \Big| \lambda du. \quad (54)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 45

equation $D \begin{pmatrix} x_1 & \dots & x_r \\ t_1 & \dots & t_r \end{pmatrix} \Big| \lambda = \int K(x_\alpha, u) D \begin{pmatrix} x_1 & \dots & x_{\alpha-1} & u & x_{\alpha+1} & \dots & x_r \\ t_1 & \dots & \dots & \dots & \dots & \dots & t_r \end{pmatrix} \Big| \lambda du$. Please remember that this $K(x_\alpha, u)$ means at α^{th} position there is a u . So α^{th} position here is replaced by this u du . So if I, so we already know that r is the index of the number λ_0 naught then this expression is not going to be, so r^{th} minor is not going to vanish. So it means that this is a non-zero quantity. So it means that this $D \begin{pmatrix} x_1 & \dots & x_r \\ t_1 & \dots & t_r \end{pmatrix} \Big| \lambda$, this r^{th} minor satisfies the homogenous Fredholm integral equation. So here we can say

(Refer Slide Time 28:58)

Substituting x at different points of the upper sequence in the minor D_r , we get r nontrivial solutions $y_j(x)$, $j = 1, 2, \dots, r$ of the homogeneous equation. These solutions are written as

$$\phi_j(x) = \frac{D_r \begin{pmatrix} x_1, & x_2, & \dots & x_{j-1}, & x, & x_{j+1}, & \dots, & x_r \\ t_1, & t_2, & \dots & \dots & \dots & \dots & \dots & t_r \end{pmatrix} \Big| \lambda_0}{D_r \begin{pmatrix} x_1, & x_2, & \dots & x_{j-1}, & x_j, & x_{j+1}, & \dots, & x_r \\ t_1, & t_2, & \dots & \dots & \dots & \dots & \dots & t_r \end{pmatrix} \Big| \lambda_0} \quad (55)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 46

that if we substitute x at the different points of the upper sequence in the minor D_r we can get our non trivial solution $y_j(x)$ which is defined like this. So here what we are doing here, we are replacing the i^{th} upper, i^{th} position of upper sequence by x and divided by D of r here

and we can say that phi of x so this ratio which is, this ratio is the function of x and we can say that this phi of x is the solution of the Fredholm integral equation which

(Refer Slide Time 29:35)

From (52), we can find the solution of the homogeneous equation (47) for the special case when $\lambda = \lambda_0$ is an eigenvalue.
 Let us suppose that $\lambda = \lambda_0$ is a zero of multiplicity k of the function $D(\lambda)$. Then the minor D_k (k^{th} order minor of $D(\lambda)$) does not identically vanish even the minors D_1, D_2, \dots, D_{k-1} may not identically vanish. Let D_r be the first minor in the sequence D_1, D_2, \dots, D_{k-1} that does not identically vanish. The number r lies between 1 and k and is the index of the eigenvalue λ_0 . Moreover $D_{r-1} = 0$. But then (52) implies that

$$D \begin{pmatrix} x_1, & \dots & x_r & | & \lambda \\ t_1, & \dots & t_r & | & \lambda \end{pmatrix} = \int K(x_\alpha, u) D \begin{pmatrix} x_1, & \dots & x_{\alpha-1}, & u, & x_{\alpha+1}, & \dots & x_r & | & \lambda \\ t_1, & \dots & \dots & \dots & \dots & \dots & \dots & | & \lambda \end{pmatrix} du. \quad (54)$$

BY ROORKEE NPTEL ONLINE CERTIFICATION COURSE 45

is homogenous here.

So here in this way we can get r number of linearly independent solution of this. Please look at here, the expression given in terms of 55, when here if I represent phi by x by that expression, then if I look at f i of x alpha, right so it means that at

(Refer Slide Time 30:00)

$\lambda = \lambda_0$ $D(\lambda_0) = 0 = D^1(\lambda_0) = \dots = D^k(\lambda_0) = 0$
 $D^k(\lambda_0) \neq 0$ k^{th} minor of $D(\lambda) \neq 0$.
 $(-1)^k D^k(\lambda_0) =$ $k-1^{\text{th}}$ minor of $D(\lambda) \neq 0$.
 Choose $1 \leq r \leq k$. index of λ_0 .
 \therefore r^{th} minor of $D(\lambda)$ does not vanish.
 but $(r-1)^{\text{th}}$ minor of $D(\lambda) = 0$.

$\phi_i(x) =$ _____
 $\phi_i(x_\alpha) =$ _____

alpha th position if we take the x alpha so it means that if I take here, if we take, phi i x alpha

(Refer Slide Time 30:11)

Substituting x at different points of the upper sequence in the minor D_r , we get r nontrivial solutions $y_i(x)$, $i = 1, 2, \dots, r$ of the homogeneous equation. These solutions are written as

$$\phi_i(x) = \frac{D_r \begin{pmatrix} x_1 & x_2 & \dots & x_{i-1} & x & x_{i+1} & \dots & x_r \\ t_1 & t_2 & \dots & \dots & \dots & \dots & \dots & t_r \end{pmatrix} \lambda_0}{D_r \begin{pmatrix} x_1 & x_2 & \dots & x_{i-1} & x_i & x_{i+1} & \dots & x_r \\ t_1 & t_2 & \dots & \dots & \dots & \dots & \dots & t_r \end{pmatrix} \lambda_0} \quad (55)$$

means, at i th position if we take x of α then this numerator is going to vanish. Because that represent that your i th row is identical to α th row here. So it means that if we take x as x α and α is not equal to i , then in that case numerator is going to vanish because of, in this determinant there are two rows which are identical to each other. But if I take the x as x i , it means here if we take x as x i , it means that $\phi_i(x)$ is, then this is, this expression is same as the expression given in denominator. So it means that in this case when x is replaced by x i then $\phi_i(x)$ is nothing but your y . So I can say that $\phi_i(x)$ is equal to zero if α not equal to i and it is equal to 1 when α is equal to i . So this

(Refer Slide Time 31:15)

$\lambda = \lambda_0 \quad D(\lambda_0) = 0 = D^1(\lambda_0) = \dots = D^k(\lambda_0) = 0$
 $D^k(\lambda_0) \neq 0$ k^{th} minor of $D(\lambda) \neq 0$.
 $(-1)^k D^k(\lambda_0) =$ $k-1^{\text{th}}$ minor of $D(\lambda) \neq 0$.
 Choose $1 \leq \alpha \leq k$ index of λ_0 .
 \therefore α^{th} minor of $D(\lambda)$ does not vanish.
 but $\alpha-1^{\text{th}}$ minor of $D(\lambda) = 0$.

$\phi_i(x) =$ _____
 $\phi_i(x_\alpha) = \begin{cases} 0 & \alpha \neq i \\ 1 & \alpha = i \end{cases}$

means that this $\phi_i(x)$ given by this is having this particular property

(Refer Slide Time 31:21)

Substituting x at different points of the upper sequence in the minor D_r , we get r nontrivial solutions $y_i(x)$, $i = 1, 2, \dots, r$ of the homogeneous equation. These solutions are written as

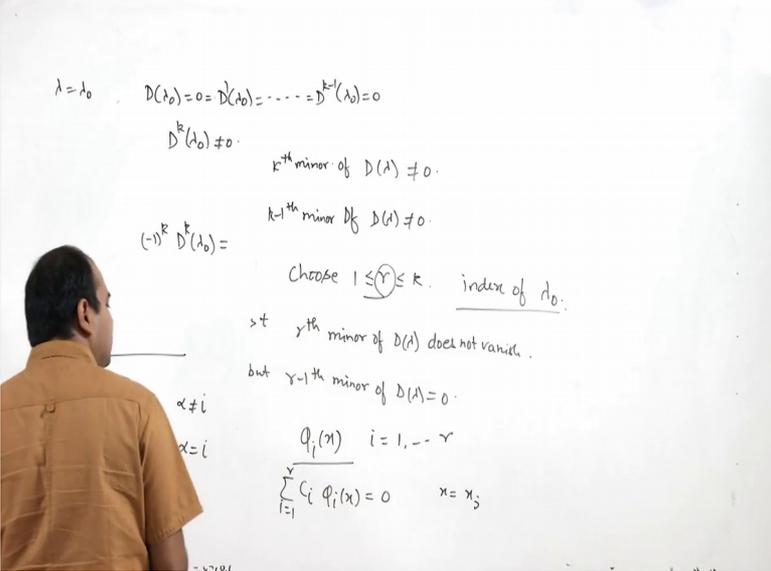

$$\phi_i(x) = \frac{D_r \begin{pmatrix} x_1 & x_2 & \dots & x_{i-1} & x & x_{i+1} & \dots & x_r \\ t_1 & t_2 & \dots & \dots & \dots & \dots & \dots & t_r \end{pmatrix} \lambda_0}{D_r \begin{pmatrix} x_1 & x_2 & \dots & x_{i-1} & x_i & x_{i+1} & \dots & x_r \\ t_1 & t_2 & \dots & \dots & \dots & \dots & \dots & t_r \end{pmatrix} \lambda_0} \quad (55)$$

46

that $\phi_i(x)$ is equal to zero when x is equal to y and equal to 1 when x is equal to y . And with the help of this property you can easily check that this solution $\phi_i(x)$ for i is equal to say 1 to say r , these are linearly independent solutions. In fact you can easily check that summation $c_i \phi_i(x)$ is equal to zero, c_i equal to 1 to r and then you can replace x equal to say, x_j and you can check that

(Refer Slide Time 31:53)

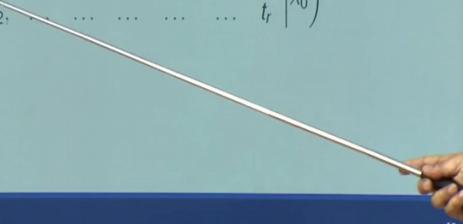

$\lambda = \lambda_0$
 $D(\lambda_0) = 0 = D^1(\lambda_0) = \dots = D^k(\lambda_0) = 0$
 $D^k(\lambda_0) \neq 0$
 x^{th} minor of $D(\lambda) \neq 0$
 $(k-1)^{\text{th}}$ minor of $D(\lambda) \neq 0$
 Choose $1 \leq r \leq k$, index of λ_0 .
 s.t. r^{th} minor of $D(\lambda)$ does not vanish.
 but $(r-1)^{\text{th}}$ minor of $D(\lambda) = 0$.
 $\alpha \neq i$
 $x = i$
 $\phi_i(x)$ $i = 1, \dots, r$
 $\sum_{i=1}^r c_i \phi_i(x) = 0$ $x = x_j$

all the corresponding coefficients c_k are equal to zero. So in this way we can say that all these solutions given by

(Refer Slide Time 32:01)

Substituting x at different points of the upper sequence in the minor D_r , we get r nontrivial solutions $y_i(x)$, $i = 1, 2, \dots, r$ of the homogeneous equation. These solutions are written as

$$\phi_i(x) = \frac{D_r \left(\begin{array}{cccc|c} x_1 & x_2 & \dots & x_{i-1} & x & x_{i+1} & \dots & x_r \\ t_1 & t_2 & \dots & \dots & \dots & \dots & \dots & t_r \end{array} \middle| \lambda_0 \right)}{D_r \left(\begin{array}{cccc|c} x_1 & x_2 & \dots & x_{i-1} & x_i & x_{i+1} & \dots & x_r \\ t_1 & t_2 & \dots & \dots & \dots & \dots & \dots & t_r \end{array} \middle| \lambda_0 \right)} \quad (55)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 46

this $\phi_i(x)$ are linearly independent.

Please remember that r is the index of $D(\lambda)$ corresponding to $\lambda = \lambda_0$. So here we can summarize the discussion in the theorem which is known as Fredholm's second theorem. It says that if λ_0 is zero

(Refer Slide Time 32:23)

Fredholm's Second Theorem

If λ_0 is a zero of multiplicity n of the function $D(\lambda)$, then the homogeneous equation

$$y(x) = \lambda_0 \int K(x, t)y(t)dt$$

possess at least one, and at most n , linearly independent solutions in terms of which every other solution is expressible linearly and homogeneously. Such a system of n independent solution is given by

$$\phi_\alpha(x) = \frac{D \left(\begin{array}{cccc|c} x_1 & x_2 & \dots & x_{\alpha-1} & x & x_{\alpha+1} & \dots & x_n \\ t_1 & t_2 & \dots & t_{\beta-1} & t_\beta & t_{\beta+1} & \dots & t_n \end{array} \middle| \lambda_0 \right)}{D \left(\begin{array}{cccc|c} x_1 & x_2 & \dots & x_n \\ t_1 & t_2 & \dots & t_n \end{array} \middle| \lambda_0 \right)} \quad (56)$$

where $i = 1, 2, \dots, n$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 47

of multiplicity n of the function $D(\lambda)$ then the homogeneous equation $y(x) = \lambda_0 \int K(x, t)y(t)dt$ possesses at least 1 and at most n linearly independent solutions in terms of which every other solution is expressible, linearly and homogeneously. And this such, this system of n independent solutions is given by the expression here, $\phi_\alpha(x) = \frac{D(x_1, x_2, \dots, x_{\alpha-1}, x, x_{\alpha+1}, \dots, x_n | t_1, t_2, \dots, t_{\beta-1}, t_\beta, t_{\beta+1}, \dots, t_n | \lambda_0)}{D(x_1, x_2, \dots, x_n | t_1, t_2, \dots, t_n | \lambda_0)}$ and this t_1 to $t_{\beta-1}$, t_β

beta and t m. And in denominator it is the nth minor of, nth Fredholm minor of D lambda. Is that Ok?

(Refer Slide Time 33:12)

Example

Solve

$$y(x) = 1 + \lambda \int_0^1 (1 - 3xt)y(t)dt. \quad (57)$$

Here

$$c_0 = 1, \quad C_0(x, t) = 1 - 3xt,$$

$$c_1 = \int_0^1 C_0(x, x)dx = \int_0^1 (1 - 3x^2)dx = 0,$$

$$C_1(x, t) = c_1 K(x, t) - \int_0^1 K(x, s)C_0(s, t)ds$$

$$= 0 - \int_0^1 (1 - 3xs)(1 - 3st)ds = -3xt + 3/2(x + t) - 1.$$

BY ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 48

And then let us consider one

(Refer Slide Time 33:14)

Fredholm's Second Theorem

If λ_0 is a zero of multiplicity n of the function $D(\lambda)$, then the homogeneous equation

$$y(x) = \lambda_0 \int K(x, t)y(t)dt$$

possess at least one, and at most n , linearly independent solutions in terms of which every other solution is expressible linearly and homogeneously. Such a system of n independent solution is given by

$$\phi_\alpha(x) = \frac{D \left(\begin{array}{c} x_1, x_2, \dots, x_{\alpha-1}, x, x_{\alpha+1}, \dots, x_n \\ t_1, t_2, \dots, t_{\beta-1}, t_\beta, t_{\beta+1}, \dots, t_n \end{array} \middle| \lambda_0 \right)}{D \left(\begin{array}{c} x_1, x_2, \dots, x_n \\ t_1, t_2, \dots, t_n \end{array} \middle| \lambda_0 \right)} \quad (56)$$

where $i = 1, 2, \dots, n$.

BY ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 47

example based on Fredholm second theorem.

So here example is y of x equal to lambda zero to 1, 1 minus t x t y t d t. If you remember we have already discussed this example with the help of Fredholm first theorem. So here we considering the homogenous equation, now as we have done in

(Refer Slide Time 33:35)

Example

Solve

$$y(x) = \lambda \int_0^1 (1 - 3xt)y(t)dt. \quad (57)$$

Here

$$c_0 = 1, \quad C_0(x, t) = 1 - 3xt,$$

$$c_1 = \int_0^1 C_0(x, x)dx = \int_0^1 (1 - 3x^2)dx = 0,$$

$$C_1(x, t) = c_1 K(x, t) - \int_0^1 K(x, s)C_0(s, t)ds$$

$$= 0 - \int_0^1 (1 - 3xs)(1 - 3st)ds = -3xt + 3/2(x + t) - 1.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 48

the previous lecture, we can calculate all the c is and you can see that your

(Refer Slide Time 33:39)

$$c_2 = \int_0^1 C_1(x, x)dx = - \int_0^1 \frac{1}{2}(-3x^2 + 3x - 1)dx = -\frac{1}{2},$$

$$C_2(x, t) = c_2 K(x, t) - 2 \int_0^1 K(x, s)C_1(s, t)ds$$

$$= -\frac{1}{2}(1 - 3xt) + 2 \int_0^1 (1 - 3xs)(-3st + 3/2(s + t) - 1)dt = 0.$$

Since $C_2(x, t)$ vanishes, from (45) we find that $C_3 = C_4 = \dots$ and $c_3 = c_4 = \dots$ also vanish. Therefore

$$D(\lambda) = \sum_{m=0}^{\infty} \frac{(-\lambda)^m}{m!} c_m$$

$$= 1 - \lambda \cdot 0 + \frac{\lambda^2 - 1}{2} = 1 - \frac{\lambda^2}{4}.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 49

D lambda is given by m equal to zero to infinity minus lambda to power m factorial m small c m and all these c is are already calculated in previous lecture. Similarly we can write it here and you can say that D lambda is nothing but 1 minus lambda square by 4. And

(Refer Slide Time 33:56)

Hence eigenvalues of (57) are

$$D(\lambda) = 0$$
$$\lambda = +2, -2.$$

Now

$$D(x, t; \lambda) = \sum_{m=0}^{\infty} \frac{(-\lambda)^m}{m!} C_m$$
$$= (1 - 3xt) - \lambda(-3xt + \frac{3}{2}(x+t) - 1)$$

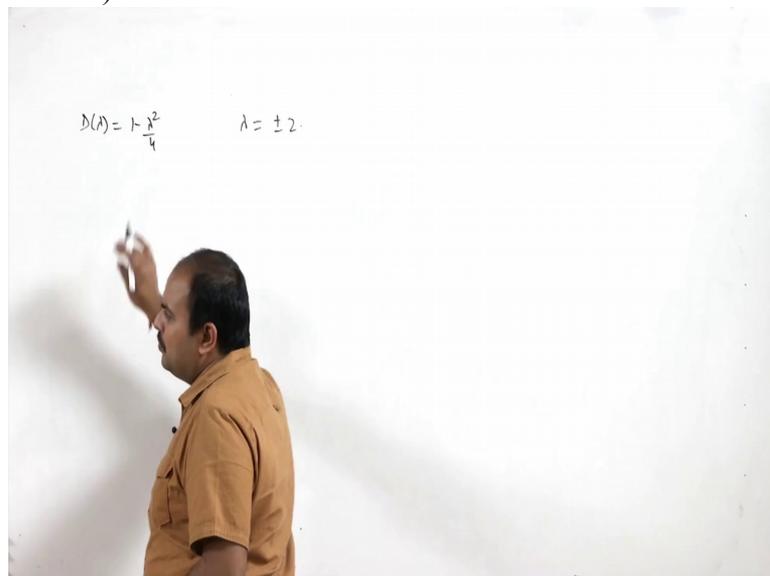

For $\lambda = 2$

$$D(x, t; \lambda) = 3[1 + xt - x - t] = 3(1 - x)(1 - t).$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 50

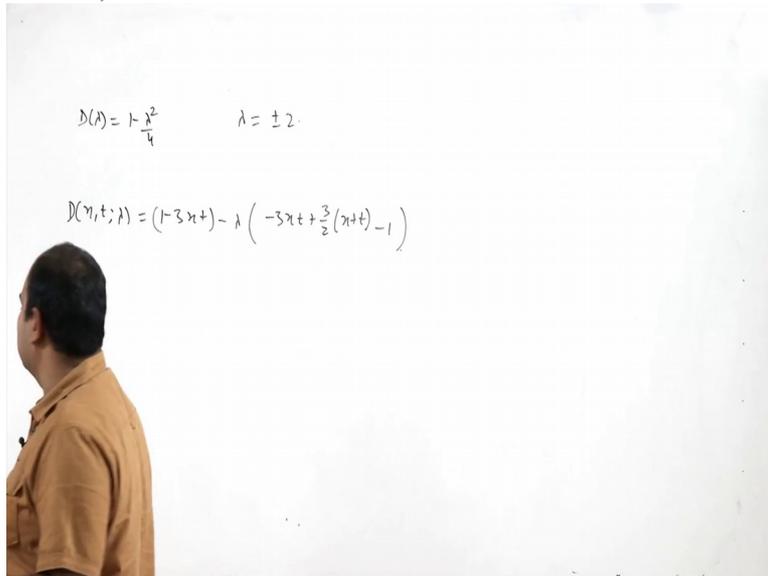

if you look at $D(\lambda)$ is equal to $1 - \lambda^2$ by 4. So if I take λ in a way such that $D(\lambda)$ is equal to zero. So let us take λ equal to plus 2 or minus 2. So we can

(Refer Slide Time 34:10)

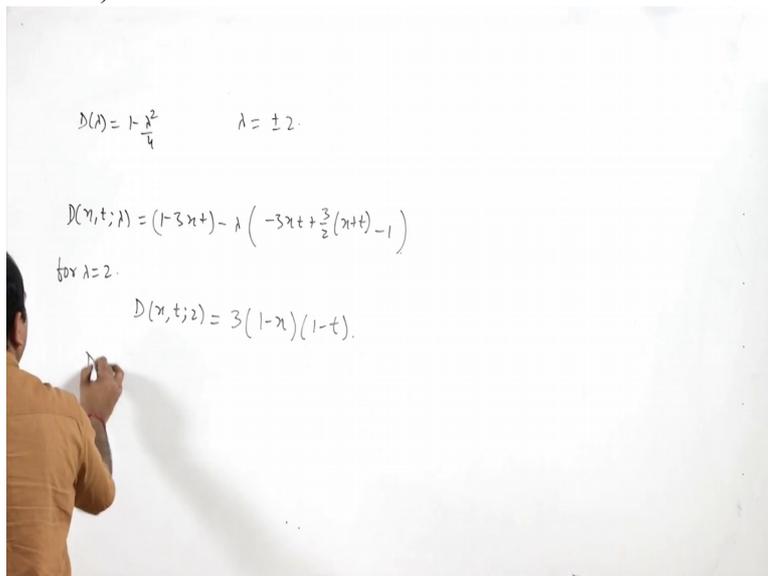

say that λ equal to plus minus 2 is known as the eigenvalues of the equation, integral equation and in this case your $D(x, t; \lambda)$ which we have already calculated, let me write it here, $D(x, t; \lambda)$ is given as $1 - 3xt + \lambda(-3xt + \frac{3}{2}(x+t) - 1)$ and when you simplify this is

(Refer Slide Time 34:38)

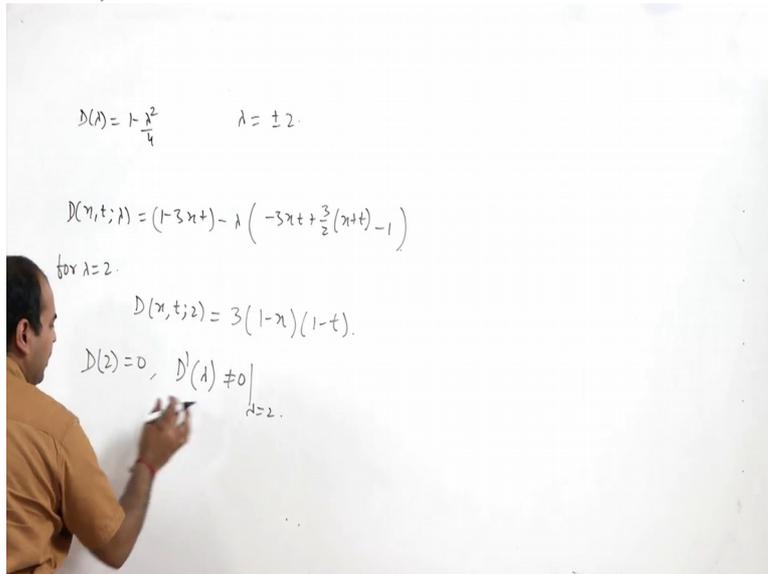

for lambda equal to 1, lambda equal to 2 $d \times t$ is given as 3 of 1 minus x 1 minus t . So it means that

(Refer Slide Time 34:51)

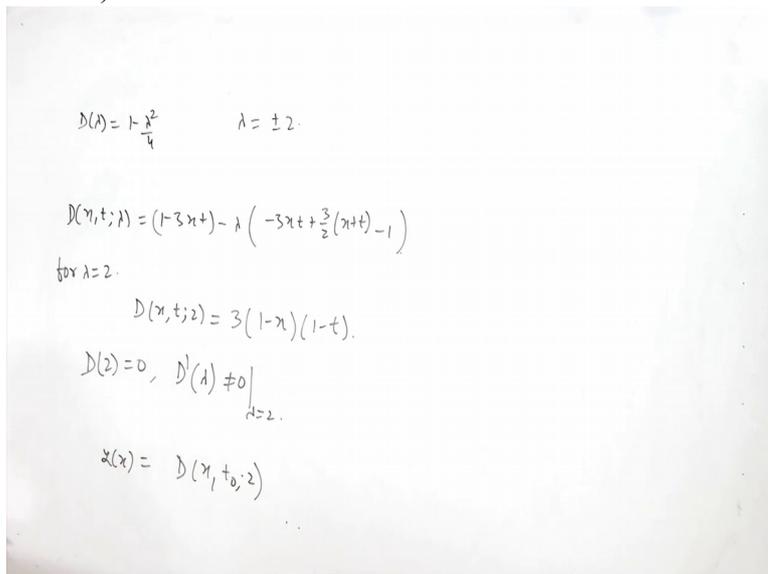

here your d of 2 is equal to zero but d dash lambda is not equal to zero at lambda equal to 2, that you can easily verify here. Then in this case we have already seen

(Refer Slide Time 35:04)

that in this case, your solution y of x is given as D of x , say some particular value of t , let us say t naught and 2, that is going to be solution of this. So here we

(Refer Slide Time 35:19)

just try to see that for λ is equal to 2, D x t λ is reduced to $3(1-x)(1-t)$ here

(Refer Slide Time 35:27)

For $\lambda = -2$

$$D(x, t, \lambda) = (1 - 3x)(3t - 1).$$

Therefore solution of homogeneous integral equation (57) corresponding to $\lambda = 2$ is given by

$$y(x) = D(x, t, \lambda) = 3[1 + xt - x - t] = 3(1 - x)(1 - t).$$

for any value of t . Let $t = s$ then it is easy to see that

$$\begin{aligned} y(x) &= 2 \int_0^1 (1 - 3xt)[(1 - s)(1 - t)] dt \\ &= 2(1 - s) \int_0^1 (1 - t - 3xt + 3xt^2) dt \\ &= (1 - s)(1 - x). \end{aligned}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 51

and for lambda equal to 2, -2 you can say that D x t lambda is given by 1 minus 3 s into 3 minus 1 So we can say that in this case if we apply the result which is Fredholm's second theorem that

(Refer Slide Time 35:41)

Fredholm's Second Theorem

If λ_0 is a zero of multiplicity n of the function $D(\lambda)$, then the homogeneous equation

$$y(x) = \lambda_0 \int K(x, t)y(t)dt$$

possess at least one, and at most n , linearly independent solutions in terms of which every other solution is expressible linearly and homogeneously. Such a system of n independent solution is given by

$$\phi_\alpha(x) = \frac{D \left(\begin{array}{cccc|c} x_1 & x_2 & \dots & x_{\alpha-1} & x & x_{\alpha+1} & \dots & x_n \\ t_1 & t_2 & \dots & t_{\beta-1} & t_\beta & t_{\beta+1} & \dots & t_n \end{array} \middle| \lambda_0 \right)}{D \left(\begin{array}{cccc|c} x_1 & x_2 & \dots & x_n \\ t_1 & t_2 & \dots & t_n \end{array} \middle| \lambda_0 \right)} \quad (56)$$

where $i = 1, 2, \dots, n$.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 47

if lambda naught is a zero of multiplicity n so here n is equal to 1. In that case we have at least 1 and at most 1. So we can say that at least 1

(Refer Slide Time 35:53)

$$c_2 = \int_0^1 C_1(x, x) dx = - \int_0^1 \frac{1}{2} (-3x^2 + 3x - 1) dx = -\frac{1}{2},$$

$$C_2(x, t) = c_2 K(x, t) - 2 \int_0^1 K(x, s) C_1(s, t) ds$$

$$= -\frac{1}{2} (1 - 3xt) + 2 \int_0^1 (1 - 3xs) (-3st + 3/2(s+t) - 1) dt = 0.$$

Since $C_2(x, t)$ vanishes, from (45) we find that $C_3 = C_4 = \dots$ and $c_3 = c_4 = \dots$ also vanish. Therefore

$$D(\lambda) = \sum_{m=0}^{\infty} \frac{(-\lambda)^m}{m!} c_m$$

$$= 1 - \lambda \cdot 0 + \frac{\lambda^2 - 1}{2} = 1 - \frac{\lambda^2}{4}.$$

49

solution is

(Refer Slide Time 35:55)

Hence eigenvalues of (57) are

$$D(\lambda) = 0$$

$$\lambda = +2, -2.$$

Now

$$D(x, t; \lambda) = \sum_{m=0}^{\infty} \frac{(-\lambda)^m}{m!} c_m$$

$$= (1 - 3xt) - \lambda(-3xt + \frac{3}{2}(x+t) - 1)$$

For $\lambda = 2$

$$D(x, t; \lambda) = 3[1 + xt - x - t] = 3(1-x)(1-t).$$

50

given and that solution you can find out by nth minor of your Fredholm, of D lambda so here first minor of D lambda is given by D x t lambda. Ok

(Refer Slide Time 36:08)

For $\lambda = -2$

$$D(x, t, \lambda) = (1 - 3x)(3t - 1).$$

Therefore solution of homogeneous integral equation (57) corresponding to $\lambda = 2$ is given by

$$y(x) = D(x, t, \lambda) = 3[1 + xt - x - t] = 3(1 - x)(1 - t).$$

for any value of t . Let $t = s$ then it is easy to see that

$$\begin{aligned} y(x) &= 2 \int_0^1 (1 - 3xt)[(1 - s)(1 - t)] dt \\ &= 2(1 - s) \int_0^1 (1 - t - 3xt + 3xt^2) dt \\ &= (1 - s)(1 - x). \end{aligned}$$

IT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 51

so here we can say that corresponding to lambda equal to 2, the solution y of x is given by D of x t lambda. So here lambda is equal to 2 and you can take any value of t. So when you put lambda equal to 2, it is reduced to 3 into 1 minus x 1 minus 2. So it means, our claim is that for any value of t, this expression 3 into 1 minus x 1 minus t is a solution of the homogenous integral equation.

So that we can verify here. So we can take let us say, t equal to s. You can take any value of t here. So let t equal to

(Refer Slide Time 36:44)

For $\lambda = -2$

$$D(x, t, \lambda) = (1 - 3x)(3t - 1).$$

Therefore solution of homogeneous integral equation (57) corresponding to $\lambda = 2$ is given by

$$y(x) = D(x, t, \lambda) = 3[1 + xt - x - t] = 3(1 - x)(1 - t).$$

for any value of t . Let $t = s$ then it is easy to see that

$$\begin{aligned} y(x) &= 2 \int_0^1 (1 - 3xt)[(1 - s)(1 - t)] dt \\ &= 2(1 - s) \int_0^1 (1 - t - 3xt + 3xt^2) dt \\ &= (1 - s)(1 - x). \end{aligned}$$

IT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 51

s and we can verify then this expression D x t lambda is going to be a solution of this. If you calculate it is coming out to be 1 minus s 1 minus x. It means that this expression gives you a

solution of your homogenous integral equation for lambda equal to 2. Similarly you can do for lambda equal to minus 2. So you can check that for lambda equal to minus 2, this expression $D(x,t) = 1 - 3xt^3 - 1$ is a solution of the homogenous integral equation for any values of t between this 0 to 1, Ok.

So let us try to find out the solution

(Refer Slide Time 37:25)

Fredholm's Third Theorem

For an inhomogeneous equation

$$y(x) = f(x) + \lambda_0 \int K(x,t)y(t)dt \quad (58)$$

to possess a solution in the case when λ_0 is a root of $D(\lambda_0)$ of index n , it is necessary and sufficient that the given function $f(x)$ be orthogonal to all the eigenfunctions $\bar{\phi}_j(x)$, $j = 1, 2, \dots, n$, of the transposed homogeneous equation corresponding to the eigenvalue λ_0 i.e.,

$$\bar{\phi}_j(x) = \lambda_0 \int K(t,x)\bar{\phi}_j(t)dt, j = 1, 2, \dots, n$$

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 52

for non-homogenous equation. So that is the content of Fredholm's third theorem which says that this inhomogenous equation or non-homogenous equation $y(x) = f(x) + \lambda_0 \int K(x,t)y(t)dt$ will have a solution in a case when λ_0 is a zero of, is a root of $D(\lambda_0)$ of index n . And the necessary and sufficient condition for this is that the function $f(x)$ is orthogonal to all the eigen function $\bar{\phi}_j(x)$ of the transpose homogenous equation. What is the transpose homogenous equation? That your $\bar{\phi}_j(x)$ is the solution of this equation $\lambda_0 \int K(t,x)\bar{\phi}_j(t)dt = 0$. So if you remember the homogenous part, the homogenous part is $\lambda_0 \int K(x,t)y(t)dt = 0$. So the transpose equation is this, $\lambda_0 \int K(t,x)\bar{\phi}_j(t)dt = 0$. So if we can find out the solution of this transpose homogenous equation with the help of Fredholm's second theorem, and $f(x)$ is orthogonal to all those $\bar{\phi}_j(x)$ then your solution is given by this, $y(x) = f(x) + \lambda_0 \int K(x,t)y(t)dt$

(Refer Slide Time 38:31)

The general solution is given by

$$y(x) = f(x) + \lambda_0 \int \frac{D \left(\begin{matrix} x, & x_1, & x_2, & \dots & x_n \\ t, & t_1, & \dots & \dots & t_n \end{matrix} \middle| \lambda_0 \right)}{D \left(\begin{matrix} x_1, & x_2, & \dots & x_n \\ t_1, & \dots & \dots & t_n \end{matrix} \middle| \lambda_0 \right)} f(t) dt$$

$$+ \sum_{p=1}^n C_p \phi_p(x).$$

53

equal to $f(x) + \lambda_0$ and if you remember we have, this is nothing but $\phi_j(x)$ here. So plus p equal to 1 to n $C_p \phi_p(x)$. So here this we can denote as say some $h(x, y, \lambda_0)$, this is kind of resolvent kernel in this particular case. And this ϕ_p is the solution of the homogenous integral

(Refer Slide Time 38:58)

Fredholm's Third Theorem

For an inhomogeneous equation

$$y(x) = f(x) + \lambda_0 \int K(x, t)y(t) dt \quad (58)$$

to possess a solution in the case when λ_0 is a root of $D(\lambda_0)$ of index n , it is necessary and sufficient that the given function $f(x)$ be orthogonal to all the eigenfunctions $\bar{\phi}_j(x)$, $j = 1, 2, \dots, n$, of the transposed homogeneous equation corresponding to the eigenvalue λ_0 i.e.,

$$\bar{\phi}_j(x) = \lambda_0 \int K(t, x)\bar{\phi}_j(t) dt, j = 1, 2, \dots, n$$

52

equation. So it means that in this case, if $f(x)$ satisfies this condition that it is orthogonal to this, and $\bar{\phi}_j$ satisfies the associated transpose equation, then solution

(Refer Slide Time 39:11)

The general solution is given by

$$y(x) = f(x) + \lambda_0 \int \frac{D \left(\begin{array}{c} x, x_1, x_2, \dots, x_n \\ t, t_1, \dots, t_n \end{array} \middle| \lambda_0 \right)}{D \left(\begin{array}{c} x_1, x_2, \dots, x_n \\ t_1, \dots, t_n \end{array} \middle| \lambda_0 \right)} f(t) dt$$
$$+ \sum_{p=1}^n C_p \phi_p(x).$$

is given by this. And so we can find with the help of Fredholm second theorems which we have discussed earlier. This is the simple generalization of Fredholm alternative theorem. So here we will stop.

And so we can summarize it like this. That Fredholm first theorem is giving you the solution method when $D \lambda_0$ is not equal to zero. And second theorem gives you the solution of Fredholm integral, Fredholm integral equation which is homogenous in the case when $D \lambda_0$ is equal to zero or you can say that λ_0 is a root of $D \lambda$ of multiplicity say m . And in Fredholm third theorem we try to find out the solution of non-homogenous integral equation. And thank you for listening us. We will meet in a next lecture. Thank you.
