**Equations with Convolution Type Kernels II**

Hello friends, I welcome you to my second lecture on equations with convolution type kernels. Let us consider the system of algebraic equations  $\phi_1(x) = 1 - 2 \int_0^x e^{2(x-t)} \phi_1(t) dt + \int_0^x \phi_2(t) dt$ . And then  $\phi_2(x) = 4x - \int_0^x \phi_1(t) dt + 4 \int_0^x (x-t) \phi_2(t) dt$ . So as we discussed in the previous lecture let us take the Laplace transform of both of these equations on both sides.

(Refer Slide Time: 00:57)

**Example 1:** Consider the system of algebraic equations

$$\phi_1(x) = 1 - 2 \int_0^x e^{2(x-t)} \phi_1(t) dt + \int_0^x \phi_2(t) dt,$$

$$\phi_2(x) = 4x - \int_0^x \phi_1(t) dt + 4 \int_0^x (x-t) \phi_2(t) dt.$$

**Solution:** Taking the Laplace transform of the above system of equations, we get

$$\Phi_1(s) = \frac{1}{s} - 2 \frac{1}{s-2} \Phi_1(s) + \frac{1}{s} \Phi_2(s)$$

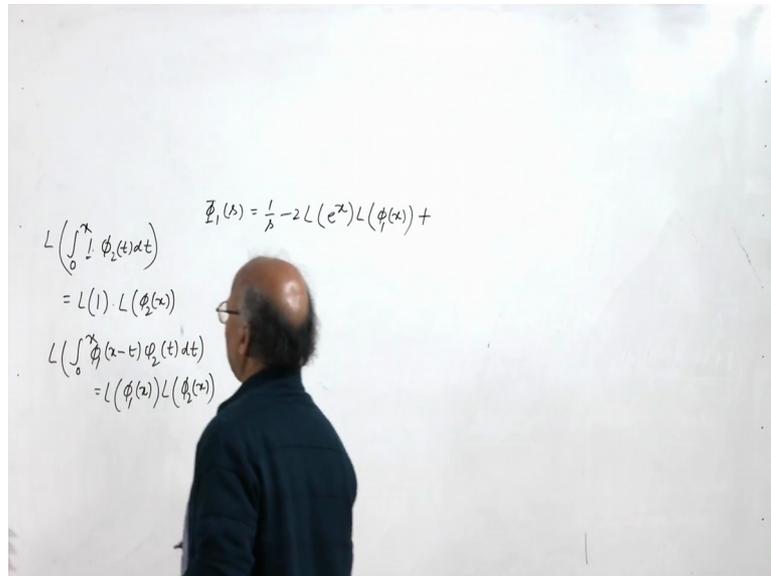

2

So what we get is when we take the Laplace transform of the first equation we get  $\phi_1(s) = \frac{1}{s} - 2 \frac{1}{s-2} \phi_1(s) + \frac{1}{s} \phi_2(s)$ . Now the third term on the right side  $\int_0^x \phi_2(t) dt$ . When we take the Laplace transform of this integral it can also be regarded as the convolution of the function 1 and  $\phi_2(t)$ .

We can write it as  $\int_0^x 1 \cdot \phi_2(t) dt$  where (con) 1 function is taken as the function 1. So Laplace transform of  $\int_0^x 1 \cdot \phi_2(t) dt$  is Laplace transform of 1 into Laplace transform of  $\phi_2(x)$ . What we are doing here when we take the Laplace

transform of integral 0 to x, phi 1 x minus t phi 2 t d t. This is Laplace transform of phi 1 x into Laplace transform of phi 2 x.

(Refer Slide Time: 02:42)

So let us take phi 1 function to be the constant function 1, okay. So let phi 1 x be equal to 1 for all x. Then phi 1 x minus t will be equal to 1, so Laplace transform of integral 0 to x, phi 2 t d t will be the product of the Laplace transform of 1 and Laplace transform of phi 2 x. So Laplace transform of 1 means 1 over s into Laplace transform of phi 2 x, so that is phi 2 s. And then when we take the Laplace transform of the second equation, Laplace transform of phi 2 is phi 2 s equal to Laplace transform x is 1 over s square.

And then minus Laplace transform of, again integral 0 to x, phi 1 t d t, its Laplace transform will be product of Laplace transform of 1 and Laplace transform of phi 1 x. And then 4 times Laplace transform of integral 0 to x, (in) x minus t into phi 2 t d t will be Laplace transform of x into Laplace transform of phi 2 t, where we have taken phi 1 x function to be x so that phi 1 x minus t is equal to x minus t. So this implies phi 1 s equal to 1 over s minus 2 over s minus 1, phi 1 s plus 1 over s, phi 2 s.

Then phi 2 s equal to 4 over s square minus 1 over s, phi 1 s plus 4 over s square, phi 2 s. Or we can write them as, let us collect the coefficient of phi 1 s. So 1 plus 2 over s minus 1 into phi 1 s minus 1 over s, phi 2 s equal to 1 over s. Second equation can be rewritten as 1 over s, phi 1 s plus 1 minus 4 over s square, phi 2 s equal to 4 over s square.

(Refer Slide Time: 05:49)

$$\begin{aligned} \bar{\phi}_1(s) &= \frac{1}{s} - 2L(e^{-x})L(\phi(x)) + \frac{1}{s}\bar{\phi}_2(s) \\ \bar{\phi}_2(s) &= \frac{4}{s^2} - L(1)L(\phi(x)) + 4L(x)L(\phi(x)) \\ \Rightarrow \bar{\phi}_1(s) &= \frac{1}{s} - \frac{2}{s-1}\bar{\phi}_1(s) + \frac{1}{s}\bar{\phi}_2(s) \\ \bar{\phi}_2(s) &= \frac{4}{s^2} - \frac{1}{s}\bar{\phi}_1(s) + \frac{4}{s^2}\bar{\phi}_2(s) \\ \text{or } (1 + \frac{2}{s-1})\bar{\phi}_1(s) - \frac{1}{s}\bar{\phi}_2(s) &= \frac{1}{s} \\ \frac{1}{s}\bar{\phi}_1(s) + (1 - \frac{4}{s^2})\bar{\phi}_2(s) &= \frac{4}{s^2} \end{aligned}$$

Simplifying we get, so  $1 + \frac{2}{s-1}$  becomes  $\frac{s+1}{s-1}$  into  $\frac{s+1}{s-1}\bar{\phi}_1(s) - \frac{1}{s}\bar{\phi}_2(s) = \frac{1}{s}$  minus  $\frac{1}{s}$ ,  $\bar{\phi}_2(s) = \frac{4}{s^2}$ . Then  $\frac{1}{s}\bar{\phi}_1(s) + (1 - \frac{4}{s^2})\bar{\phi}_2(s) = \frac{4}{s^2}$ . Now these two are linear equations in  $\bar{\phi}_1(s)$  and  $\bar{\phi}_2(s)$ .

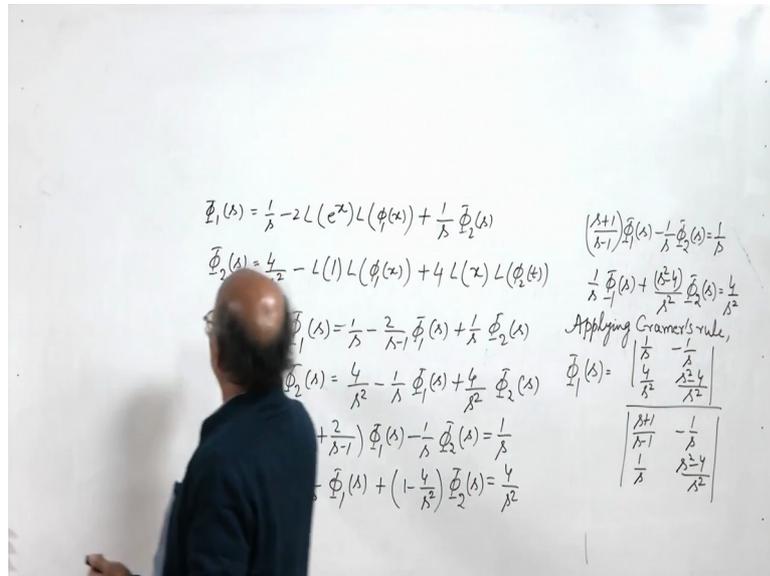

(Refer Slide Time: 06:47)

$$\begin{aligned} \bar{\phi}_1(s) &= \frac{1}{s} - 2L(e^{-x})L(\phi(x)) + \frac{1}{s}\bar{\phi}_2(s) \\ \bar{\phi}_2(s) &= \frac{4}{s^2} - L(1)L(\phi(x)) + 4L(x)L(\phi(x)) \\ \Rightarrow \bar{\phi}_1(s) &= \frac{1}{s} - \frac{2}{s-1}\bar{\phi}_1(s) + \frac{1}{s}\bar{\phi}_2(s) \\ \bar{\phi}_2(s) &= \frac{4}{s^2} - \frac{1}{s}\bar{\phi}_1(s) + \frac{4}{s^2}\bar{\phi}_2(s) \\ \text{or } (1 + \frac{2}{s-1})\bar{\phi}_1(s) - \frac{1}{s}\bar{\phi}_2(s) &= \frac{1}{s} \\ \frac{1}{s}\bar{\phi}_1(s) + (1 - \frac{4}{s^2})\bar{\phi}_2(s) &= \frac{4}{s^2} \end{aligned}$$

We can solve them for the values of  $\bar{\phi}_1(s)$  and  $\bar{\phi}_2(s)$ . So let us apply Cramer's rule. So applying Cramer's rule  $\bar{\phi}_1(s)$  will be equal to determinant  $\frac{1}{s}$ ,  $\frac{4}{s^2}$  and then minus  $\frac{1}{s}$ ,  $\frac{4}{s^2}$  divided by  $s^2$  over determinant of the coefficient

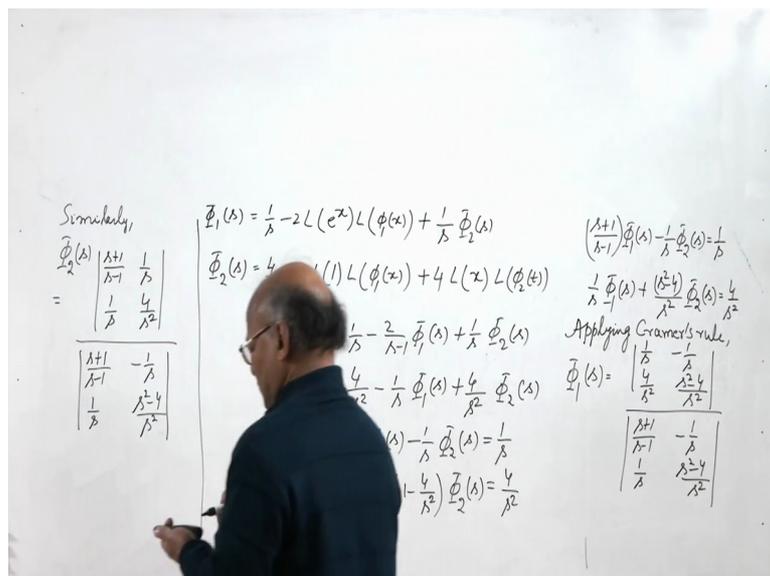

matrix. So s plus 1 over s minus 1 minus 1 over s and we have 1 over s, s square minus 4 over s square. So this gives you the value of phi 1 s.

(Refer Slide Time: 07:55)

Similarly phi 2 s we can write. Phi 2 s will be equal to determinant s plus 1 over s minus 1, 1 over s and then 1 over s, second column will be 1 over s, 4 by s square divided by determinant of s plus 1 over s minus 1, 1 over s minus 1 over s, s square minus 4 divided by s square.

(Refer Slide Time: 08:47)

Now we can evaluate the values of these determinants and then we will see that after we simplify the expressions of  $\phi_1(s)$  and  $\phi_2(s)$  and then take the inverse Laplace transform you will see that  $\phi_1(x)$  comes out to be  $e^{-x} - xe^{-x}$ .

$\phi_2(x)$  comes out to be  $\frac{8}{9}e^{-2x} + \frac{1}{3}xe^{-x} - \frac{8}{9}e^{-x}$ . after simplifying  $\phi_1(s)$  and  $\phi_2(s)$ , we will have to break them into partial fractions and then we will have to take the inverse Laplace transform of  $\phi_1(s)$  and  $\phi_2(s)$  to arrive at the solution of the given system of Volterra integral equations of second kind.

(Refer Slide Time: 09:47)

$$\Phi_2(s) = \frac{4}{s^2} - \frac{1}{s}\Phi_1(s) + \frac{4}{s^2}\Phi_2(s).$$

Taking inverse Laplace transform, we get

$$\phi_1(x) = e^{-x} - xe^{-x}$$

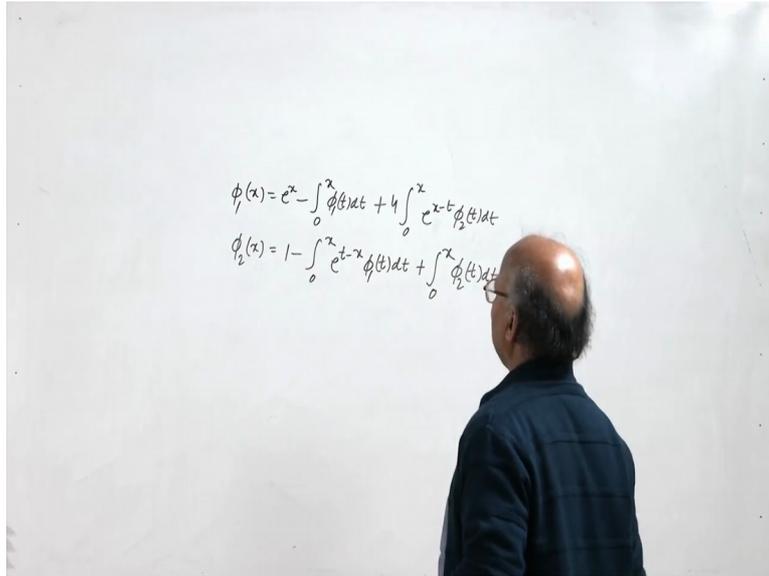

$$\phi_2(x) = \frac{8}{9}e^{-2x} + \frac{1}{3}xe^{-x} - \frac{8}{9}e^{-x}.$$

3

So how we do this? Let us take another example. So here we are given another system of algebraic equations,  $\phi_1(x) = e^{-x} - \int_0^x \phi_1(t) dt + 4 \int_0^x e^{-x+t} \phi_2(t) dt$  and then  $\phi_2(x) = 1 - \int_0^x e^{-x+t} \phi_1(t) dt + \int_0^x \phi_2(t) dt$ .

(Refer Slide Time: 10:53)

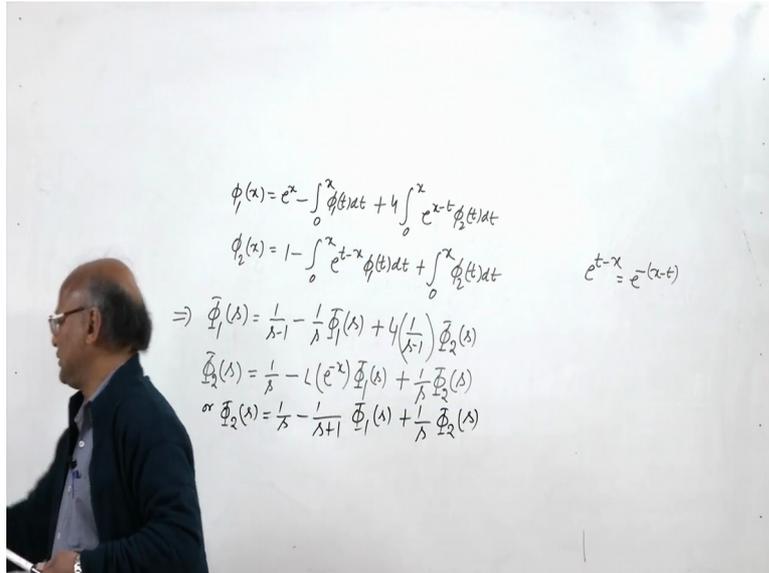

Again let us take the Laplace transform of both of these equations on both sides. So (fa) we get the Laplace transform of the first equation gives you  $\phi_1(s)$  equal to Laplace transform of  $e^{-x}$  which is  $1/(s+1)$  minus Laplace transform of  $\int_0^x \phi_1(t) dt$ . So this can be regarded as  $1/s$  into  $\phi_1(s)$  and therefore Laplace transform of 1 which is  $1/s$  into Laplace transform of  $\phi_1(x)$  which is  $\phi_1(s)$  plus 4 times Laplace transform of  $e^{-x}$  to the power  $x$  function.

So this is  $1/(s+1)$  and then Laplace transform of  $\phi_2(x)$ , so that is  $\phi_2(s)$ . And then second equation gives Laplace transform of  $\phi_2(x)$  is  $\phi_2(s)$ , Laplace transform of 1 is  $1/s$ . Now here we have  $e^{-x-t}$ . So we will have to write it as  $e^{-x}$  to the power  $t-x$  we have to write as  $e^{-x-t}$ . So we will have Laplace transform of  $e^{-x-t}$  into Laplace transform of  $\phi_1(x)$  which is  $\phi_1(s)$ .

And then we have Laplace transform of 1 which is  $1/s$  into  $\phi_2(s)$ . Now what we will do is, or  $\phi_2(s)$  can be written as  $1/s - 1/s + 1$ ,  $\phi_1(s) + 1/s$ ,  $\phi_2(s)$ . Let us now write it as an algebraic equation in  $\phi_1(s)$  and  $\phi_2(s)$ , linear system.

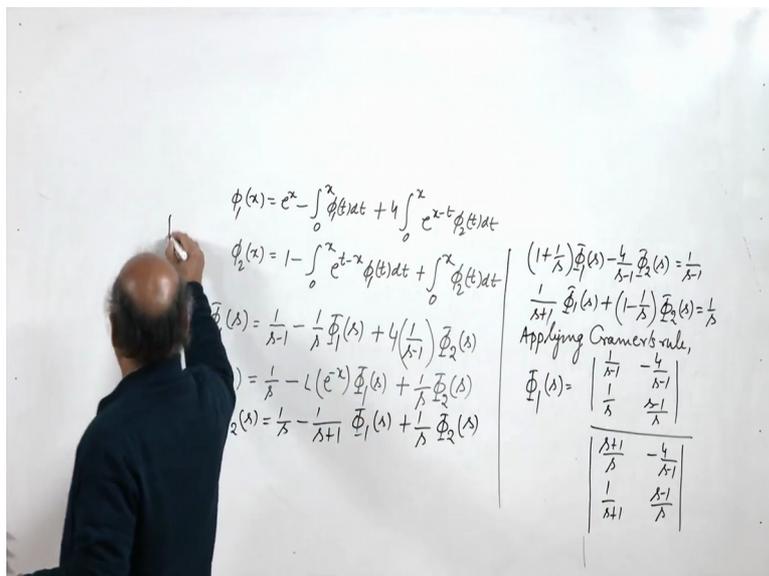

(Refer Slide Time: 13:02)

So we will have let us say pick up the first equation so,  $1 + 1$  by  $s$  into  $\phi_1$   $s$  minus  $4$  upon  $s$  minus  $1$  into  $\phi_2$   $s$  equal to  $1$  over  $s$  minus  $1$ . The second equation gives you  $1$  over  $s$  plus  $1$  into  $\phi_1$   $s$  plus  $1$  minus  $1$  upon  $1$  by  $s$ ,  $1$  minus  $1$  upon  $s$  into  $\phi_2$   $s$  equal to  $1$  upon  $s$ . Again let us simplify or let us solve this system of linear algebraic equations in  $\phi_1$   $s$  and  $\phi_2$   $s$  by applying Cramer's rule.

So  $\phi_1$   $s$ , let us write first the expression for  $\phi_1$   $s$ .  $\phi_1$   $s$  will be  $1$  over  $s$  minus  $1$ ,  $1$  over  $s$ , then minus  $4$  upon  $s$  minus  $1$  and we have  $1$  minus  $1$  upon  $s$ . So that is  $s$  minus  $1$  upon  $s$  divided by  $s$  plus  $1$  over  $s$ . We have  $1$  over  $s$  plus  $1$ , then we have minus  $4$  upon  $s$  minus  $1$  and then we have  $s$  minus  $1$  upon  $s$ . So if you simplify it further what we get?

(Refer Slide Time: 15:10)

So let us see the value of the determinant in the numerator. So  $1$  over  $s$  minus  $1$  into  $s$  minus  $1$  over  $s$ . So we get  $1$  over  $s$  minus, minus  $4$  upon  $s$  minus  $1$  into  $1$  by  $s$ . So we get plus  $4$  upon  $s$  into  $s$  minus  $1$ . Then we have in the denominator,  $s$  square minus  $1$  by  $s$  square and we have plus  $4$  upon  $s$  square minus  $1$ . So how much is this? In the numerator we get  $s$  into  $s$  minus  $1$ , then we have  $s$  minus  $1$  plus  $4$ . So we get  $s$  plus  $3$  divided by  $s$  square into  $s$  square minus  $1$ .

So what we have is  $s$  square minus  $1$  whole square plus  $4$   $s$  square. So this is  $s$  plus  $3$  upon  $s$  into  $s$  minus  $1$  and then we get  $s$  square,  $s$  square minus  $1$  divided by,  $s$  square minus  $1$  whole square plus  $4$   $s$  square is  $s$  square plus  $1$  whole square, so we get this. We can write it further as  $s$  into  $s$  plus  $3$ , this is  $s$  minus  $1$  into  $s$  plus  $1$ , so  $s$  plus  $1$  divided by  $s$  square plus  $1$  whole square.

(Refer Slide Time: 17:21)

$$= \frac{\frac{1}{s} + \frac{4}{s(s-1)}}{\frac{s^2-1}{s^2} + \frac{4}{s^2-1}}$$

$$= \frac{s+3}{s(s-1)}$$

$$= \frac{s+3}{s^2(s-1)}$$

$$= \frac{s+3}{s^2(s-1)}$$

$$= \frac{s+3}{s^2(s-1)}$$

$$\phi_1(x) = e^{-x} - \int_0^x \phi_2(t) dt + 4 \int_0^x e^{-x-t} \phi_2(t) dt$$

$$\phi_2(x) = 1 - \int_0^x e^{-t-x} \phi_1(t) dt + \int_0^x \phi_2(t) dt$$

$$\Rightarrow \bar{\phi}_1(s) = \frac{1}{s} + \frac{4}{s(s-1)} \bar{\phi}_2(s)$$

$$\bar{\phi}_2(s) = \frac{1}{s-1} - \frac{1}{s} \bar{\phi}_1(s) + \frac{1}{s} \bar{\phi}_2(s)$$

$$\left(1 + \frac{1}{s}\right) \bar{\phi}_1(s) - \frac{4}{s-1} \bar{\phi}_2(s) = \frac{1}{s-1}$$

$$\frac{1}{s+1} \bar{\phi}_1(s) + \left(1 - \frac{1}{s}\right) \bar{\phi}_2(s) = \frac{1}{s}$$

Applying Cramer's rule,

$$\bar{\phi}_1(s) = \begin{vmatrix} \frac{1}{s+1} & -\frac{4}{s-1} \\ \frac{1}{s} & \frac{s-1}{s} \end{vmatrix}$$

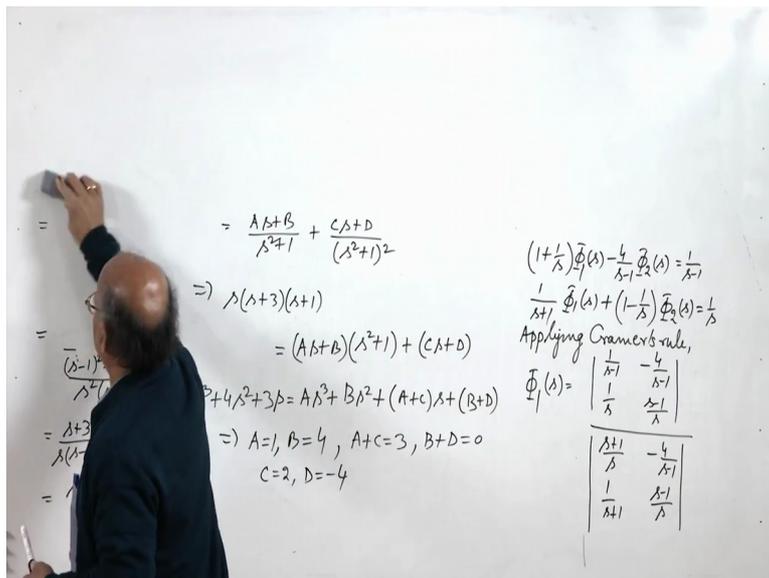

$$\begin{vmatrix} \frac{s+1}{s} & -\frac{4}{s-1} \\ \frac{1}{s+1} & \frac{s-1}{s} \end{vmatrix}$$

Now what we do is I am doing this problem because it is a bit too complicated. So we have this further equal to  $A s + B$  upon  $s^2 + 1$  plus  $C s + D$  upon  $s^2 + 1$  whole square. Let us break this into partial fractions. So then we have the identity  $s^2 + 3$  into  $s^2 + 1$  equal to  $A s + B$  into  $s^2 + 1$  plus  $C s + D$ . Let us multiply, so we get here  $A s^3 + B s^2 + A s + B + C s + D$ .

So  $A + C$  into  $s^3 + B + D$ . In the left hand side what we will have? This is  $s^3 + 3 s^2 + s^2 + 4 s$ . So  $s^3 + 4 s^2 + 3$ . Now this is an identity, so let us equate the coefficients of like powers of  $s$ . So this gives you  $A$  equal to 1, equating the coefficients of  $s^3$ .  $B$  equal to 4, equating the coefficients of  $s^2$ . Now equating the coefficients of this is  $3 s$ . So equating the coefficients of  $s$  we have  $A + C$  equal to 3 and we have  $B + D$  equal to 0. So we have four equations.

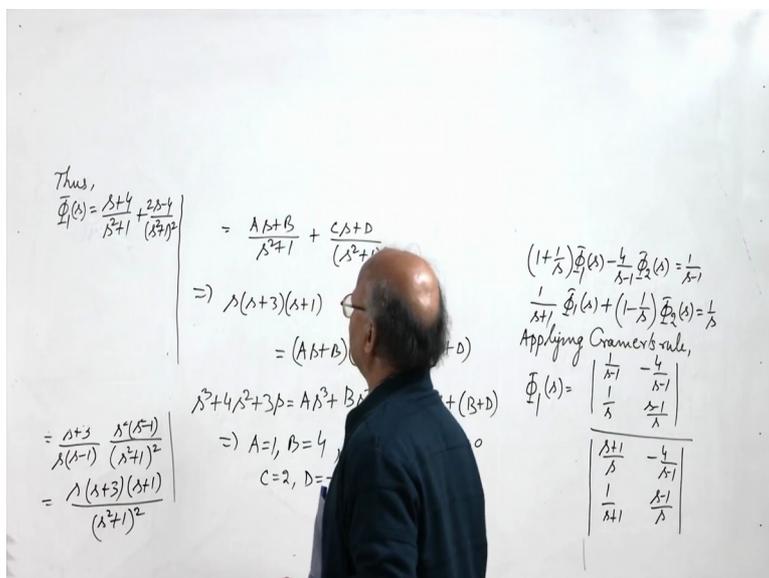

We will have the values of all the four  $A, B, C, D$ . So  $A$  equal to 1 gives you  $C$  equal to 2 and  $B$  equal to 4 gives you  $D$  equal to minus 4.

(Refer Slide Time: 19:53)

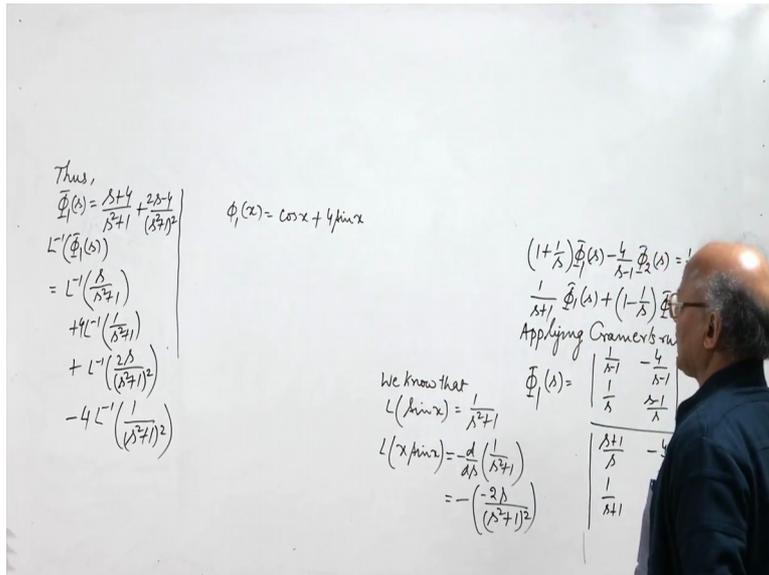

So thus we have phi 1 s equal to A s plus B upon s square plus 1. A means 1 and B is 4. So s plus 4 divided by s square plus 1. C is equal to 2 so 2 s minus 4 divided by s square plus 1 whole square, this is phi 1 s.

(Refer Slide Time: 20:37)

Now let us take inverse Laplace transform of this. So inverse Laplace transform of phi 1 s gives you inverse Laplace transform of, now let us break it into two parts. S over s square plus 1 plus inverse Laplace transform of 4 times, 4 we can take outside, 1 over s square plus 1. Then inverse Laplace transform of 2 s upon s square plus 1 whole square, then inverse

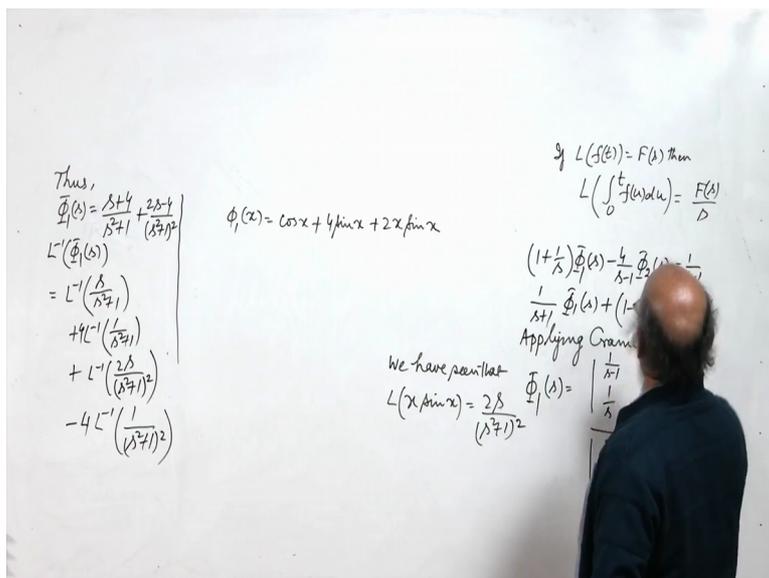

So L inverse of  $\frac{2s}{s^2+1}$  is  $2x \sin x$ . Now let us find the inverse Laplace transform of  $\frac{1}{s^2+1}$ . So we have just now seen that Laplace transform of  $x \sin x$  is equal to  $\frac{2s}{s^2+1}$ . Now we want inverse Laplace transform of  $\frac{1}{s^2+1}$ .

So we have to find formula which divides the Laplace transform of a function by  $s$ . So if we know that if  $\mathcal{L}\{f(t)\} = F(s)$  then Laplace transform of  $\int_0^t f(u) du$  is equal to  $\frac{F(s)}{s}$ .

(Refer Slide Time: 24:04)

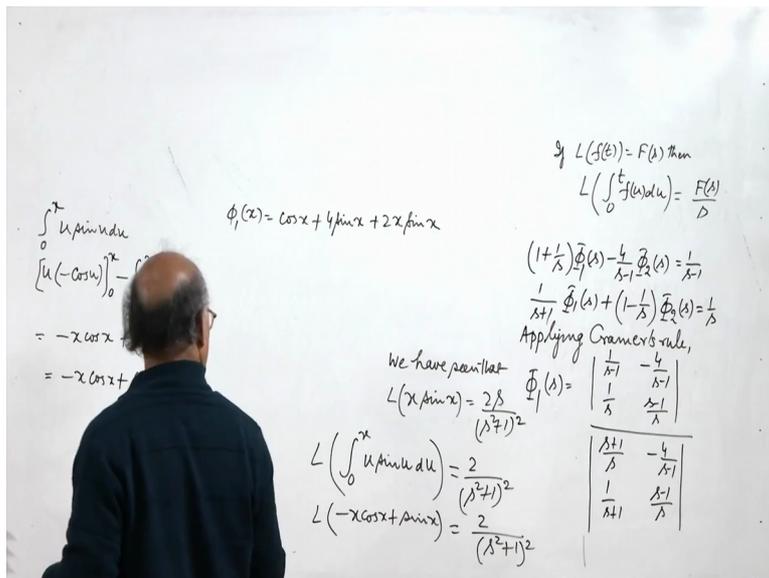

So if you want to divide this function of  $s$  by  $s$  you need to integrate this function  $x \sin x$  over the interval  $0$  to  $t$ . So what we will have?  $\int_0^t u \sin u du$ . by our

formula Laplace transform of this is nothing but  $F(s)$  by  $s$  that is  $\frac{2}{s^2 + 1}$  whole square. So let us see what is this integral  $\int_0^t u \sin u \, du$ ? So  $u$  times integrate by parts so minus  $\cos u$   $\int_0^t$ , I think we should take integral here because we are writing in terms of  $x$  so let us write here limit  $0$  to  $x$ .

So  $\int_0^x$  minus  $\int_0^x$ , derivative of  $u$  is  $1$ , then we have minus  $\cos u \, du$ . So this will be equal to minus  $x \cos x$  and when you put  $0$  it is  $0$ . Here we have plus, integral of  $\cos u$  is  $\sin u$ . So what we get is minus  $x \cos x$  plus  $\sin x$ . So this means what? Laplace transform of minus  $x \cos x$  plus  $\sin x$ , this is equal to  $\frac{2}{s^2 + 1}$  whole square.

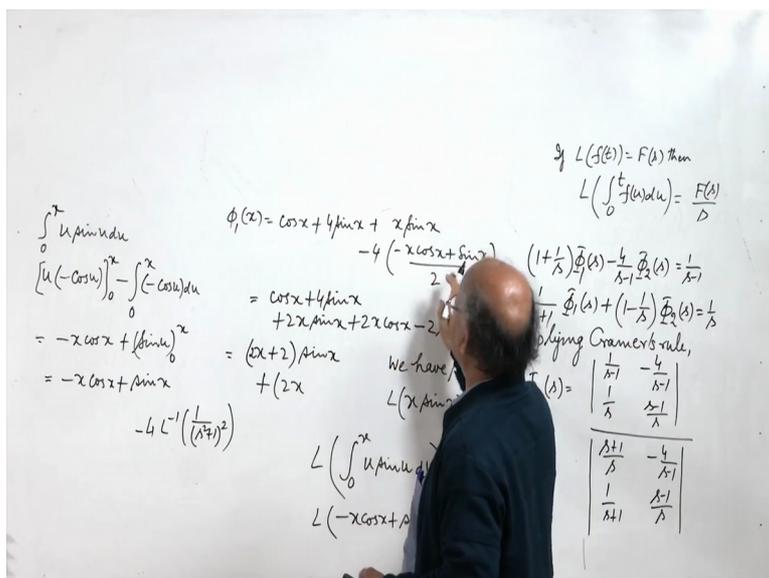

(Refer Slide Time: 26:19)

Now what we have, I have omitted that. the expression I have omitted. I think it was minus 4. We had minus 4 L inverse of 1 upon s square plus 1 whole square. So what we have? L inverse of 1 over s square plus 1 whole square is minus x cos x plus sin x by 2. So minus 4 minus x cos x plus sin x divided by 2, okay. So what is this? This is equal to right.

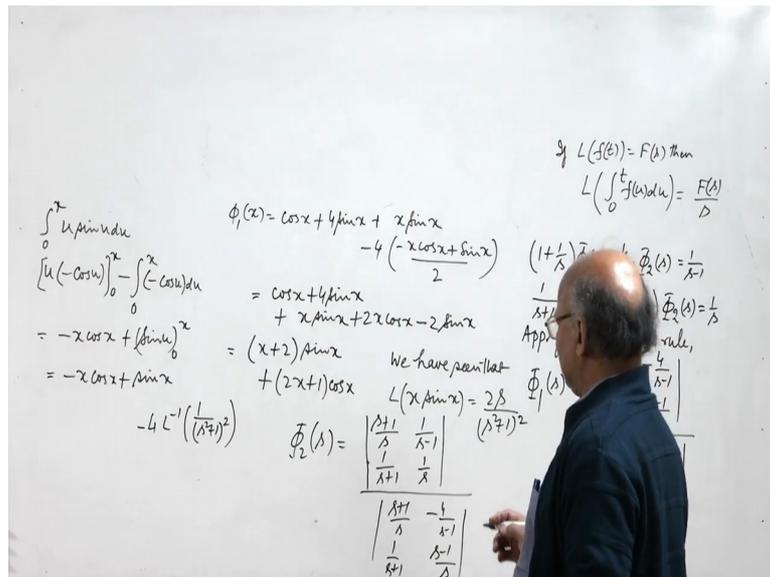

So cos x plus 4 sin x and then we have 2 x sin x and here we have minus-minus plus 2 x cos x and we have minus 2 sin x. So there is a mistake here. This is cos x plus 4 sin x plus x sin x minus this.

(Refer Slide Time: 27:39)

Now we have  $\cos x$  plus  $4 \sin x$  plus  $x \sin x$  and then we have  $2x \cos x$  minus  $2 \sin x$ . So we will have here  $x$  plus  $2 \sin x$  and then  $2x$  plus  $1 \cos x$  which is your function  $\phi_1 x$ . Similarly we can find  $\phi_2 x$ .  $\phi_2 x$  will be given by  $\phi_2 s$  is equal to determinant  $s$  plus  $1$  by  $s$  and then we have  $1$  over  $s$  plus  $1$ , we have  $1$  over  $s$  minus  $1$  and then we have  $1$  over  $s$  here divided by  $s$  plus  $1$  by  $s$  minus  $4$  by  $s$  minus  $1$ ,  $1$  over  $s$  plus  $1$ ,  $s$  minus  $1$  by  $s$ .

(Refer Slide Time: 28:56)

So we can solve these determinants, obtain the expressions for  $\phi_2 s$  and then take the inverse Laplace transform. We have to make the partial fractions on the right hand side. So just like I did for the function  $\phi_1 x$ , similarly we can do it for the function  $\phi_2 x$  and we will have the value of  $\phi_2 x$  as  $2 + x$  by  $2 \cos x$  minus  $2x$  plus  $1$  by  $2 \sin x$ . So this is how we solve the system of Volterra type integral equations of second kind.

(Refer Slide Time: 29:26)

$$\Phi_2(s) = \frac{1}{s} - \frac{1}{s+1} \Phi_1(s) + \frac{1}{s} \Phi_2(s).$$

Taking inverse Laplace transform, we get

$$\phi_1(x) = (x+2)\sin x + (2x+1)\cos x$$
$$\phi_2(x) = \left(\frac{2+x}{2}\right)\cos x - \left(\frac{2x+1}{2}\right)\sin x.$$

IT ROORKEE NITEL ONLINE CERTIFICATION COURSE 5

Now let us go to Volterra integral equation of the first kind of the convolution type. So here let us consider an integral equation of the first kind,  $\int_0^x K(x-t)y(t)dt = f(x)$  where  $y(t)$  is the unknown function,  $f(x)$  and the kernel  $K(x-t)$  is known.

So where kernel  $K(x-t)$  is dependent solely on the difference  $x-t$  of the arguments it is called an integral equation of the first kind of convolution type. Now if you recall when we did the first lecture on linear integral equations there we had discussed how the linear integral equations arise in the study. So there the first equation that we had discussed was the Abel's integral equation and that Abel's integral equation which arises by a problem in mechanics is an integral equation of this type.

(Refer Slide Time: 30:25)

### Volterra integral equation of the first kind of the convolution type

An integral equation of the first kind

$$\int_0^x K(x-t)y(t)dt = f(x), \quad \dots(1)$$

whose Kernel  $K(x,t)$  is dependent solely on the difference  $(x-t)$  of arguments is called an integral equation of the first kind of convolution type.

For instance, this class of equations includes the generalized Abel's equation.

Let  $L(f(x))=F(s)$ ,  $L(K(x))=\tilde{K}(s)$  and  $L(y(x))=Y(s)$  .

So that is an example of integral equation of the first kind of convolution type. Now so here (1a) Laplace transform of  $f(x)$  is  $F(s)$ ,  $L(K(x))$  is  $\tilde{K}(s)$  and  $L(y(x))$  is equal to  $Y(s)$ . Then we will have by taking the Laplace transform on both sides of equation 1 and utilising again the convolution theorem, Laplace transform of the left hand side by convolution theorem will be  $\tilde{K}(s)Y(s)$  equal to  $F(s)$ .

And then assuming  $\tilde{K}(s)$  is not equal to 0 we can determine the value of  $Y(s)$ .  $Y(s)$  is equal to  $F(s)$  by  $\tilde{K}(s)$  where  $\tilde{K}(s)$  is not 0. Then the solution of the linear integral equation is obtained by taking the inverse Laplace transform of this equation. So  $L^{-1}$  of  $Y(s)$  gives us  $y(x)$  and  $L^{-1}$  of  $F(s)$  over  $\tilde{K}(s)$  gives us the solution of the given integral equation.

(Refer Slide Time: 31:27)

Taking the Laplace transform of both sides of equation (1) and utilizing the convolution theorem, we have

$$\begin{aligned} \tilde{K}(s)Y(s) &= F(s) \\ Y(s) &= \frac{F(s)}{\tilde{K}(s)}, \quad (\tilde{K}(s) \neq 0). \end{aligned}$$

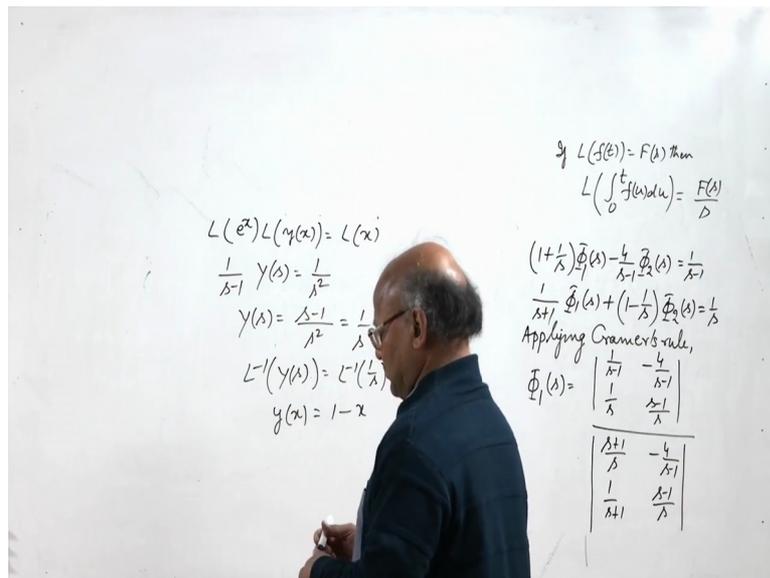

The solution  $y(x)$  of the integral equation (1) is then found by taking the inverse Laplace of  $Y(s)$  i.e.

$$y(x) = L^{-1}(Y(s)).$$

Now let us take an example. Suppose we have the integral equation  $0 \leq t < \infty$ ,  $e^{-t} * y(t) = x(t)$ . Let us take the Laplace transform of both sides. So Laplace transform of this by convolution theorem will be Laplace transform of  $e^{-t}$  into Laplace transform of  $y(t)$ . So Laplace transform of  $e^{-t}$  into Laplace transform of  $y(t)$  equal to Laplace transform of  $x(t)$ . So this gives you  $\frac{1}{s-1} Y(s) = \frac{1}{s^2}$ .

Or we can say  $Y(s) = \frac{s-1}{s^2}$ . We can break it into parts. So  $\frac{1}{s-1} - \frac{1}{s}$ . So L inverse of  $Y(s)$  is L inverse of  $\frac{1}{s-1} - \frac{1}{s}$ . And what we get is  $y(t) = 1 - e^{-t}$ .

(Refer Slide Time: 32:39)

So in taking inverse Laplace transform we get the solution of the given convolution type integral equation of first kind. Now let us go to one more problem. The integral 0 to x, sin hyperbolic x minus t, phi t d t equal to x cube into e to the power minus x.

(Refer Slide Time: 32:58)

**Example 2 :** Consider 
$$\int_0^x \sinh(x-t)\phi(t)dt = x^3 e^{-x}.$$

**Solution :** Taking the Laplace transform of both the sides, we get

$$\Phi(s) = 6 \left[ \frac{1}{(s+1)^2} - \frac{2}{(s+1)^3} \right],$$

taking the inverse Laplace transform, we get

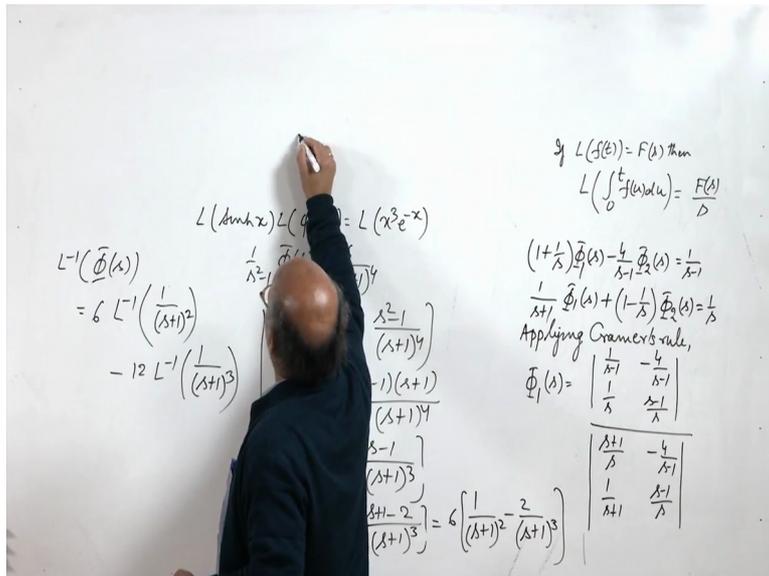

$$\phi(x) = 6(xe^{-x} - x^2 e^{-x}).$$

IIT ROORKEE NIPER ONLINE CERTIFICATION COURSE 9

So here again let us take the Laplace transform on both sides. So Laplace transform of 0 to x, sin hyperbolic x minus t, phi t d t is Laplace transform of sin hyperbolic x into Laplace transform of phi x equal to Laplace transform of x cube e to the power minus x. Laplace transform of sin hyperbolic x is equal to e to the power x minus e to the power minus x by 2 and Laplace transform sin hyperbolic x is 1 by 2, Laplace transform of e to the power x

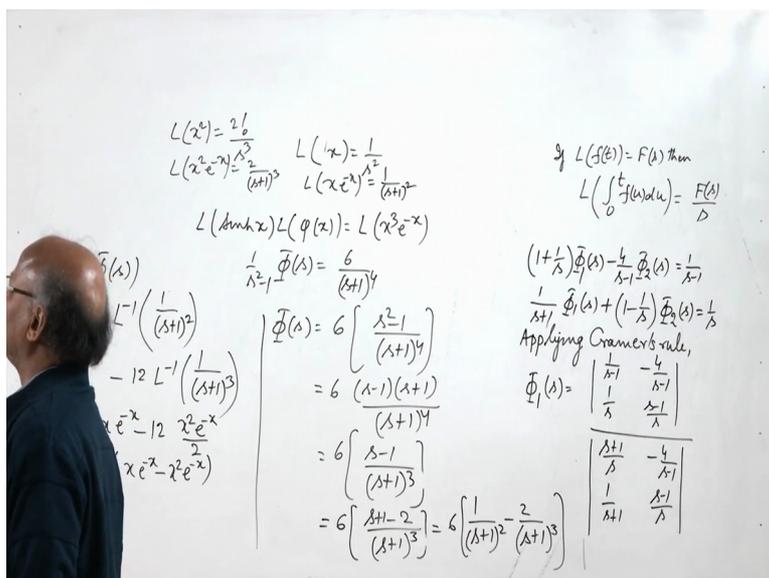

(Refer Slide Time: 36:49)

Now Laplace transform of  $x$  is  $1$  over  $s$  square and Laplace transform of  $x e$  to the power minus  $x$  is  $1$  over  $s$  plus  $1$  whole square. So this is  $6$  times  $x$  into  $e$  to the power minus  $x$ . Laplace transform of  $x$  square is  $2$  factorial by  $s$  cube and Laplace transform of  $x$  square  $e$  to the power minus  $x$  is  $2$  upon  $s$  plus  $1$  whole cube. So this is minus  $12$  times,  $L$  inverse of  $1$  over  $s$  plus  $1$  whole cube will be  $x$  square  $e$  to the power minus  $x$  divided by  $2$ .

So we get  $6$  times  $x e$  to the power minus  $x$  minus  $x$  square  $e$  to the power minus  $x$ . So this is how we get the solution of the integral equation of first kind of convolution type.

With that I would like to conclude my lecture. Thank you very much for your attention.
