Lecture – 55
Basic theorems on eigenvalues and QR method

Hello friends, welcome to this lecture. In this lecture we will discuss some Eigen pairs, Eigenvalue problem and some elementary properties of Eigen pairs. Also we will discuss basic QR method to find out Eigenvalues of a given matrix. So, let us start, say discussing the lecture here.

(Refer Slide Time: 00:47)

Eigen-pairs

Definition

Let A be a real $n \times n$ matrix, then λ is an eigenvalue of A , if there exists a nonzero vector x such that

$$Ax = \lambda x.$$

In this case, the vector x is called a right eigenvector or simply an eigenvector of A corresponding to the eigenvalue λ , and the pair (λ, x) is called an eigenpair of A .

We say that a vector $y \in \mathbb{C}^n$ is a left eigenvector of A corresponding to λ if

$$y^H A = \lambda y^H$$

where $y^H = \bar{y}^T$ is the conjugate transpose of y .

IIIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

So, first we define what is Eigen pairs. So, let A be a real n cross n matrix, then λ is an Eigenvalue of A , if they exist a non 0 vector x such that Ax equal to λx . So, in this case the vector x is called a right eigenvector or simply an eigenvector of A , corresponding to the Eigenvalue λ and the pairs this λ and x , is known as Eigen pair of matrix A .

This Eigen, finding the Eigenvalue of A given matrix and eigenvector of A given matrix, is very very important say problem in linear algebra. In fact, many a times when you discuss differential equation or say difference equation or buckling problem, there are many more problem, where your system a your say finding say solution of the given system is reduced to finding the say Eigenvalue of a given matrix.

For example if we want to consider the stability of a solution of a linear system, then we convert our system into $\dot{x} = Ax$, where x is a vector state vector. And when we write $\dot{x} = Ax$ then any stability of any solution is governed by the behavior of the Eigenvalue of the matrix A so, that is why the problem Eigenvalue problem, finding the Eigenvalue of a given matrix is very very important problem. So, in this lecture we will discuss what is Eigen pairs and how to find out what are the properties of Eigen pairs and how to find out eigen value of a given matrix.

So, we have defined λx as an Eigen pair of A , if $Ax = \lambda x$ is here and we say that a vector y is a left eigenvector of A corresponding to the Eigenvalue λ , if $y^H A = \lambda y^H$. Here y^H is a conjugate transpose of y , is the conjugate transpose of y . So, based on the definition of Eigen pair now we observe certain things.

(Refer Slide Time: 03:06)

Remark
If λ is a real eigenvalue, then the corresponding eigenvector x is real. If λ is a complex eigenvalue, then:

- 1 $\bar{\lambda}$, the conjugate of λ , is also an eigenvalue of A ;
- 2 the eigenvector x corresponding to λ is complex; and
- 3 \bar{x} , the conjugate of x , is an eigenvector of A corresponding to $\bar{\lambda}$.

Remark
From the above definition, it is immediate the eigenvalues of A are the roots of its characteristic polynomial, denoted by $p_A(\lambda)$, and defined by $p_A(\lambda) = \det(A - \lambda I)$. Thus, the eigenvalues of A are roots of the characteristic equation of A defined by

$$p_A(\lambda) = \det(A - \lambda I) = 0$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

First that if λ is a real Eigenvalue then the corresponding eigenvector is also real, and if λ is a complex Eigenvalue, then $\bar{\lambda}$, which is the conjugate conjugate of λ is also an Eigenvalue of A and the eigenvector x corresponding to λ is complex, and \bar{x} the conjugate of x is an eigenvector of A corresponding to $\bar{\lambda}$; that is quite trivial.

(Refer Slide Time: 03:32)

Eigen-pairs

Definition

Let A be a real $n \times n$ matrix, then λ is an eigenvalue of A , if there exists a nonzero vector x such that

$$Ax = \lambda x.$$

In this case, the vector x is called a right eigenvector or simply an eigenvector of A corresponding to the eigenvalue λ , and the pair (λ, x) is called an eigenpair of A .

We say that a vector $y \in \mathbb{C}^n$ is a left eigenvector of A corresponding to λ if

$$y^H A = \lambda y^H$$

where $y^H = \bar{y}^T$ is the conjugate transpose of y .

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

When you consider this problem Ax equal to λx and if we take the conjugate transpose you can conjugate you can see that it is true. Now, second remark is that from the above definition it is immediate, that the Eigenvalues of A are the roots of its characteristic polynomial and characteristic polynomial it is denoted by $p_A(\lambda)$ and it is defined as a determinant of $\lambda I - A$, this is the Eigenvalues of A are the roots of the characteristic equation of A defined by $p_A(\lambda) = 0$, where $p_A(\lambda)$ is equal to determinant of $\lambda I - A$.

In some book you find that characteristic polynomials are defined as determinant of $\lambda I - A$. So, here we may have, in some book it is determinant of $A - \lambda I$ and in some books it is determinant of $\lambda I - A$, but in finding the problem of Eigenvalues of A given matrix whatever definition you will take, it is just a root of characteristic equation and characteristic equation is determinant of $A - \lambda I$ is equal to 0 here.

(Refer Slide Time: 04:41)

Remark

If x is an eigenvector of A corresponding to an eigenvalue λ , then so is αx for any $\alpha \neq 0$, because

$$A(\alpha x) = \alpha(Ax) = \alpha(\lambda x) = \lambda(\alpha x)$$

Also, if x_1 and x_2 are eigenvectors of A corresponding to the eigenvalue λ , then so is $x_1 + x_2$, because

$$A(x_1 + x_2) = Ax_1 + Ax_2 = \lambda x_1 + \lambda x_2 = \lambda(x_1 + x_2)$$

Thus, if we define

$$E_\lambda = \{x \in \mathbb{C}^n : Ax = \lambda x, x \in \mathbb{C}^n\}$$

then E_λ is a subspace of \mathbb{C}^n corresponding to λ , called the eigenspace corresponding to the eigenvalue λ .

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

And we also saw that that the Eigen, we try to define what is Eigen space. So, if x is an eigenvector of A corresponding to an eigenvalue λ . Then αx is also an Eigen vector corresponding to the same Eigen Eigenvalue λ . So, $A \alpha x$ equal to αAx ; that is due to linearity and Ax is nothing, but λx . So, we can write $A \alpha x$ equal to $\lambda \alpha x$

So, it means that if x is an eigenvector corresponding to λ then any non0 constant multiple of x is also an eigenvector corresponding to this λ . And similarly if x_1 and x_2 are two eigenvectors of A corresponding to the Eigenvalue λ , then we can also show that $x_1 + x_2$ is also an Eigen eigenvector corresponding to the same Eigenvalue λ .

So, that we can verify easily that $A(x_1 + x_2)$ is equal to $Ax_1 + Ax_2$ and x_1 is λx_1 , because x_1 is an eigenvector corresponding to λ . Similarly x_2 is λx_2 and if we take λ common then it is $\lambda(x_1 + x_2)$. So, it means that if x_1, x_2 are eigenvector of A corresponding to λ , then $x_1 + x_2$ is also an eigenvector corresponding to λ

So, we have seen that if x is an eigenvector of A then αx is also an eigenvector of A and $x_1 + x_2$ if x_1 and x_2 are eigenvectors of A corresponding to the Eigenvalue λ , then $x_1 + x_2$ is also an eigenvector corresponding to the same Eigenvalue λ

So, here we can say that $x_1 + x_2$ is an eigenvector and constant multiple of x is also an eigenvector. So, we can define a set E_λ which consists of all those x in \mathbb{C}^n such that $Ax = \lambda x$, then this set E_λ is a subspace of \mathbb{C}^n corresponding to the eigenvalue λ , and it is called as Eigen space corresponding to the Eigenvalue λ .

So, basically E_λ is what? E_λ is the set of all the eigenvectors including 0. So, it means that, it contains all the Eigenvalue eigenvectors corresponding to λ and the 0 vector. 0 vector is not an eigenvector corresponding to λ , but it is ok. So, it is basically the set of all eigenvectors corresponding to λ union 0.

(Refer Slide Time: 07:14)

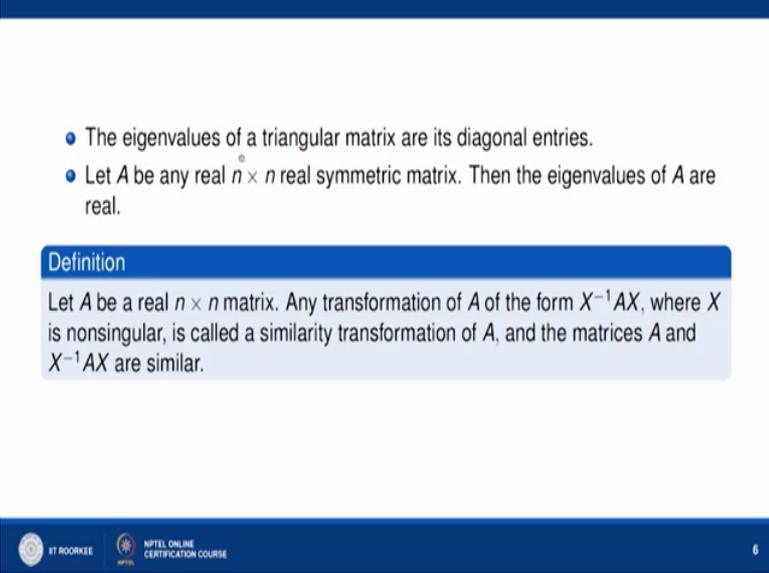

- The sum of the eigenvalues of A is called the trace of A and is denoted by $\text{trace}(A)$ or $\text{Tr}(A)$.
- If (λ, x) is an eigenpair of A , then $(\frac{1}{\lambda}, x)$ is an eigenpair for A^{-1} .
- If (λ, x) is an eigenpair of A , then $(\lambda - \mu, x)$ is an eigenpair for $A - \mu I$, where μ is a scalar.
- The set of all eigenvalues of A is called the spectrum of A , and is denoted by $\text{eig}(A)$.

Now, based on this we have certain more remarks that the sum of the Eigenvalues of A is called the trace of A and it is denoted by trace of A or $\text{Tr}(A)$. And similarly we can also define that the product of all the Eigenvalues of A is known as determinant of A . So, determinant of A you can calculate by taking the product of all the Eigenvalues of the matrix same. And if (λ, x) is an Eigen pair of A then $(\frac{1}{\lambda}, x)$ is an Eigen pair of A^{-1} .

So, here when we define $(\frac{1}{\lambda}, x)$ or we define A^{-1} then we assume that none of the Eigenvalue is a 0 Eigenvalue. So, that is why we are able to define $(\frac{1}{\lambda}, x)$. So, it means that that if (λ, x) is an Eigen pair of A then $(\frac{1}{\lambda}, x)$ is an Eigen pair of A^{-1} .

Now, next remark is that if λ, x is an Eigen pair of A then $\lambda - \mu, x$ is an Eigen pair from $A - \mu I$, where μ is any scalar, and the set of all Eigenvalues of A is called the spectrum of A and it is denoted by $\sigma(A)$. So, that gives you the spectrum of all the Eigenvalues of matrix same.

(Refer Slide Time: 08:28)

• The eigenvalues of a triangular matrix are its diagonal entries.

• Let A be any real $n \times n$ real symmetric matrix. Then the eigenvalues of A are real.

Definition

Let A be a real $n \times n$ matrix. Any transformation of A of the form $X^{-1}AX$, where X is nonsingular, is called a similarity transformation of A , and the matrices A and $X^{-1}AX$ are similar.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

And the Eigenvalues of a triangular matrix are its diagonal entry. So, if we have a triangular matrix or diagonal matrix, then the diagonal entries are nothing, but the Eigenvalues of a given matrix. And let A be any real n cross n real symmetric matrix then the Eigenvalues of A are real.

Now, we also define a similarity transformation what is that, let A be a real n cross n matrix, then any transformation of A of the form $X^{-1}AX$, where X is nonsingular is called a similarity transformation of A and the matrix A and $X^{-1}AX$ are similar right and.

(Refer Slide Time: 09:06)

Remark. Let A and B be similar matrices, i.e. suppose that

$$B = X^{-1}AX$$

where X is nonsingular. Since

$$p_B(\lambda) = \det(B - \lambda I) = \det(X^{-1}AX - \lambda I) = \det(A - \lambda I) = p_A(\lambda)$$

it is immediate that A and B have same eigenvalues. Thus, we may hope that by a suitable similarity transformation, we can reduce A to a simple form such as an upper Hessenberg form B , and thus compute the eigenvalues of A . However, note that this calculation is ill-conditioned if $\kappa_2(X)$ is large. Indeed, if

$$f(X^{-1}AX) = X^{-1}AX + E$$

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

Here we say that let A and B be similar matrices, it means that B and A are related by this relation that B can be written as X inverse AX . Then our claim is that Eigenvalues of B A and B will share the same Eigenvalues

So, here we can say that $p_B(\lambda)$, which is nothing, but determinant of B minus λI . Now here we can replace B by X inverse AX minus λI can be written as X inverse X . So, determinant of X inverse AX minus λI X inverse X , and if we take the X inverse and X common here then it is nothing, but determinant of A minus λI and which is nothing, but the characteristic polynomial of matrix A

So, it means that characteristic polynomial corresponding to B and characteristic polynomial of A are same, when B and A are similar matrices. So, it means that it is immediate that A and B have same Eigenvalues. Thus we may hope that by a suitable similarity transformation we can reduce A to a simple form; such as an upper Hessenberg form A B and thus compute the Eigenvalues of A .

So, this we will give you an idea how to find out the Eigenvalue of A given matrix. So, so by suitable transformation we try to convert our matrix into a triangular matrix or A diagonal matrix. And once it is converted in to a triangular matrix or diagonal matrix, then the diagonal entries of the reduced form it will give you the Eigenvalue of the matrix A .

But here we, we may note one thing that that in this calculation we may create some kind of error, because if we look at the computer representation of the matrix X inverse AX then it is nothing, but X inverse AX plus some error and this error is basically written as.

(Refer Slide Time: 11:10)

then it can be established that

$$\|E\|_2 \approx \mu \kappa_2(X) \|A\|_2$$

where μ is the machine precision. Thus, if $\kappa_2(X)$ is large, then we will have significant round-off errors. However, if X is orthogonal, then $\kappa_2(X) = 1$, and so we have

$$\|E\|_2 \approx \mu \|A\|_2$$

Thus, we see that $\|E\|_2$ is a small number if we work with an orthogonal similarity transformation $X^{-1}AX$. Therefore, to minimize the round-off errors in eigenvalue calculations, we work with orthogonal similarity transformations, whenever possible.

This condition number of X and two norm of A and μ , where μ is the machine precision and here X is the matrix, which we are considering here for this similarity transformation.

(Refer Slide Time: 11:23)

Remark. Let A and B be similar matrices, i.e. suppose that

$$B = X^{-1}AX$$

where X is nonsingular. Since

$$p_B(\lambda) = \det(B - \lambda I) = \det(X^{-1}AX - \lambda I) = \det(A - \lambda I) = p_A(\lambda)$$

it is immediate that A and B have same eigenvalues. Thus, we may hope that by a suitable similarity transformation, we can reduce A to a simple form such as an upper Hessenberg form B , and thus compute the eigenvalues of A . However, note that this calculation is ill-conditioned if $\kappa_2(X)$ is large. Indeed, if

$$f(X^{-1}AX) = X^{-1}AX + E$$

Now, if this condition number of this a matrix X is large, then we can say that this error is quite large. So, this procedure is done in efficient manner, if we choose our matrix X anyway such that this condition number X is very small or you can say that we have already seen that if X is orthogonal, then condition number of this orthogonal matrix is 1.

So, we can say that in this case the two norm of E is nothing, but mu times two norm of A and this is a. So, if we can say that this two norm of error matrix is a small. And if we work with an orthogonal similarity transformation $X^{-1}AX$, then the error is not going to increase. So, therefore, to minimize the round off errors in Eigenvalue calculation, we work with orthogonal similarity transformation whenever it is possible. Of course, it may not be possible for all the time, but whenever it is possible we always try to hunt for orthogonal similarity transformation.

(Refer Slide Time: 12:37)

Definition

We say that a square matrix A is diagonalizable if there exists a nonsingular matrix X such that

$$X^{-1}AX = \begin{bmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_n \end{bmatrix}$$

We say that a square matrix A is orthogonally diagonalizable if there exist an orthogonal matrix X such that X^TAX is a diagonal matrix.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 9

Now, we define the diagnosable matrices. So, we say that a square matrix A is diagnosable if they exist a nonsingular matrix X ; such that X inverse AX is a diagonal matrix and we say that a square matrix A is orthogonally diagonalize diagonalizable, if they exist an orthogonal matrix X ; such that X transpose AX is diagonal matrix. So, it means that it is diagonalizable, if we have a nonsingular matrix X as $A X X$ inverse AX is a D matrix, diagonal matrix and orthogonally diagonalizable, if this matrix X is an orthogonal matrix.

(Refer Slide Time: 13:15)

Theorem
Let A be a real $n \times n$ matrix. Then:

- (a) A is diagonalizable if and only if A has a set of n linearly independent eigenvectors.
- (b) A is orthogonally diagonalizable if and only if A is a symmetric matrix.

Remark
Let A be a real $n \times n$ square matrix. Then A need not be diagonalizable. Even if A is diagonalizable, it is not easy to determine the eigenvalues of A by finding a similarity transformation $X^{-1}AX$ that brings A to a diagonal form, because finding such an X really amounts to finding a set of n linearly independent eigenvectors of A .

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

Now, we have some result on diagonalizability. Here I am just giving without any proof that you can see in any good book of linear algebra. So, here the result is says that let A be a real n cross n matrix, then A is diagonalizable if and only if A has set of n linearly independent eigenvectors. So, diagonalizable is possible if and only if we have n linearly independent eigenvector, where n is the size of the matrix M and A is orthogonally diagonalizable if and only if A is a symmetric matrix.

So, if A is a symmetric matrix then it is orthogonally diagonalizable and if A has a n linearly independent eigenvectors, then also A is diagonalizable. And next remark is that let A be real n cross n matrix, then A need not be diagnosable, it may not possible, because one such possible case is that we do not have n linearly independent eigenvectors. So, in that case A not may not be diagonalizable.

Then even if A is not diagonalizable, even if A is diagonalizable, it is not easy to find out the Eigenvalues of a by finding this similarity transformation X inverse AX , because here we what we have seen is that similarity matrices have same number of, same Eigenvalue, but to convert this X inverse AX you know in a diagonal form.

It is not easy, because we have to calculate the nonsingular matrix as X and that we can calculate only when we have n linearly independent eigenvectors of A . Basically this X is nothing, but the column matrix of consisting eigenvectors of the matrix A . So, when

we have n linearly independent eigenvectors then we can construct X such that, say v_1 to v_n , where all these v_1 to v_n are eigenvectors of the matrix A ok.

Next is a real Schur Form Theorem. So, if A is real $n \times n$ matrix then they exist.

(Refer Slide Time: 15:27)

Real Schur Form Theorem:
 If A is a real $n \times n$ matrix, then there is an $n \times n$ real orthogonal matrix Q such that

$$Q^T A Q = R = \begin{bmatrix} R_{11} & R_{12} & \cdots & R_{1k} \\ 0 & R_{22} & \cdots & R_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & R_{kk} \end{bmatrix} \quad (1)$$

where each diagonal block R_{ii} is either a real 1×1 matrix or a real 2×2 matrix with a pair of complex conjugate eigenvalues. The diagonal blocks R_{ii} may be arranged in any prescribed order. (The matrix R in (1) is called the real Schur form of A .)

ET ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

They exist an $n \times n$ real orthogonal matrix Q ; such that $Q^T A Q$ is R , where R is this block triangular matrix here. So, here this block matrices R_{ii} is either a real one cross one matrix or real 2 cross 2 matrix with a pair of complex conjugate Eigenvalues.

So, our aim is to when, whenever we try to find out say 1 Eigenvalue of a given matrix, we try to use this real Schur Form Theorem and try to convert our matrix A into this. We need to find out a orthogonal matrix Q ; such that $Q^T A Q$ can be reduced to in this form and the diagonal blocks R_{ii} may be arranged in any prescribed order, and the matrix R here is known as real Schur Form of A .

So, that is the basic point to consider QR, QR say QR method to find out the Eigenvalue of the matrix A . So, we will discuss it later.

(Refer Slide Time: 16:31)

The Gersgorin Disk Theorems

Theorem

Gersgorin's First Theorem: Let $A = (a_{ij})_{n \times n}$. Define

$$r_i = \sum_{\substack{j=1 \\ j \neq i}}^n |a_{ij}|, \quad i = 1, 2, \dots, n$$

Then each eigenvalue λ of A satisfies at least one of the following inequalities:

$$|\lambda - a_{ii}| \leq r_i, \quad i = 1, 2, \dots, n$$

In other words, all the eigenvalues of A can be found in the union of disks $\{z : |z - a_{ii}| \leq r_i, i = 1, 2, \dots, n\}$.

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

Now, here certain more result based on say localization of the Eigenvalues. So, here we discuss two theorem given by Gersgorin Disk Theorem. So, first theorem of Gersgorin is this, that let A is a $n \times n$ matrix. We can define r_i as summation j equal to 1 to n $|a_{ij}|$, where j is not equal to i . So, other than the diagonal entry, we find out the sum of the absolute term of the i th row here.

So, that we denote as r_i . Then each Eigenvalue λ of A satisfied at least one of the following inequalities; that is modulus of $\lambda - a_{ii}$ is less than or equal to r_i or we can say that all the Eigenvalues of matrix A can be found in the union of this, this D_i ; such that modulus of $z - a_{ii}$ is less than or equal to r_i , where i is from 1 to n .

So, at least this will give you an a bound with that your Eigenvalue will lie in which kind of disk.

(Refer Slide Time: 17:37)

Definition
The disks $R_i = \{z : |z - a_{ii}| \leq r_i, i = 1, 2, \dots, n\}$ are called **Gersgorin disks** in the complex plane.

Theorem
Gersgorin's Second Theorem: Suppose that r Gersgorin disks are disjoint from the rest, then exactly r eigenvalues of A lie in the union of r disks.

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

So, that will just give you an idea and the disk R_i , which is defined as z such that the modulus of z minus a_{ii} is less than or equal to R_i , where i is running from 1 to n are known as Gersgorin disks in the complex plane.

And the second theorem says that if suppose that R Gersgorin disks are disjoint from the rest, then exactly R Eigenvalues of A lie in the union of R disks. So, it means that if we have R disjoint Gersgorin disks then every Gersgorin disk will contain one Eigenvalue of matrix A .

(Refer Slide Time: 18:16)

Example

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 3 & 4 & 9 \\ 1 & 1 & 1 \end{pmatrix}$$
$$r_1 = 5$$
$$r_2 = 12$$
$$r_3 = 2$$

The Gersgorin disks are

$$R_1 : \{z : |z - 1| \leq 5\}$$
$$R_2 : \{z : |z - 4| \leq 12\}$$
$$R_3 : \{z : |z - 1| \leq 2\}$$

(The eigenvalues of A are $7.3067, -0.6533 \pm 0.3471 i$)

IFT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

So, let us consider the example based on this Gersgorin disk theorems. So, first let us consider this a as $\begin{pmatrix} 1 & 0.1 & 0.2 \\ 0.2 & 4 & 0.3 \\ 0.4 & 0.5 & 8 \end{pmatrix}$ then if you look at the first Gersgorin disk; that is, if this is a diagonal entry one. So, based on removing this one we have 2 plus 3. So, it means that R_1 is 5 and if you look at the R_2 remove this 4. So, 3 plus 9 R_2 is 12 and here diagonal entry is 1.

So, R_3 is going to be 1 plus 1. So, that is 2. So, it means that R_1 is what, z minus the diagonal entry that is 1 less than or equal to R_1 ; that is 5 here. R_2 is z minus 4 4 is the diagonal entry here less than or equal to R_2 that is 12 and R_3 is z set of all z ; such that modulus of z minus 1 is less than or equal to 2.

So, here we have three Gersgorin disks and it is defined like this. And if we calculate the Eigen values of the matrix using MATLAB or some other means, we can say that the Eigenvalues of a is coming out to be 7.3067 minus 0.5, 0.6533 plus minus 0.347 I and you can see that it is all lying inside your the Gersgorin disk R_2 . So, that will give an idea that where your Eigenvalues will lie.

(Refer Slide Time: 19:39)

Example

$$A = \begin{pmatrix} 1 & 0.1 & 0.2 \\ 0.2 & 4 & 0.3 \\ 0.4 & 0.5 & 8 \end{pmatrix}$$

The Gersgorin disks are

$$R_1 : \{z : |z - 1| \leq 0.3\}$$

$$R_2 : \{z : |z - 4| \leq 0.5\}$$

$$R_3 : \{z : |z - 8| \leq 0.9\}$$

All the three disks are disjoint from each other. Therefore, by second theorem, each disk must contain exactly one eigenvalue of A . This is indeed true. Note that the eigenvalues of A are 0.9834, 3.9671 and 8.0495

15

Similarly, look at the example based on the second Gersgorin theorem that if A is given as $\begin{pmatrix} 1 & 0.1 & 0.2 \\ 0.2 & 4 & 0.3 \\ 0.4 & 0.5 & 8 \end{pmatrix}$ and we have a matrix like this, then Gersgorin disks are defined as z minus 1 less than or equal to 0.3 and from second Gersgorin z minus 4 less than or equal to 0.5 and z minus 8 less than or equal to 0.9.

And if you look at, if we draw these three Gersgorin disk and we can see that these disks are disjoint to each other. So, all the three disks are disjoint from each other and we know that this matrix A must have three, say complex Eigenvalues. So, we can say that by second theorem of Gersgorin we can say that each disk must contain exactly one Eigenvalue of A and that we can check through MATLAB or some other means.

We can say that the Eigenvalues of A in this case is it is coming out 0.9834 which lies in the disk are one, 3.9671 which lies inside your disk R 2 and 8.0495 which lie in disk R 3. So, here we can say that since R 1 R 2 R 3 are all disjoint. So, we can say that each and each disk will contain at least one Eigenvalue of the matrix A..

So, in this way, these localization theorems are important.

(Refer Slide Time: 21:03)

Theorem
For any consistent pair of matrix - vector norms, we have

$$\lambda \leq \|A\|$$

where λ is an eigenvalue of A. In particular, $\rho(A)$, the spectral radius of A, is bounded by $\|A\|$: $\rho(A) \leq \|A\|$.

Corollary

$$\rho(A) \leq \|A^T\|$$

Combining these two results and taking the infinity norm in particular, we obtain the next theorem.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 16

Now, next result which we have already discussed that, for any consistent pair of matrix vector vectors norm we have lambda less than or equal to norm of A, that we have discussed in the lecture of vector in matrix norm. So, there we have discussed it norm. In fact, we have proved something more; that is spectral radius of matrix A is less than or equal to A. By spectral radius of A is denoted as maximum of all the Eigenvalues of the matrix A.

(Refer Slide Time: 21:45)

Theorem

$$\rho(A) \leq \min\left\{\max_i \sum_{j=1}^n |a_{ij}|, \max_j \sum_{i=1}^n |a_{ij}|\right\}$$

Theorem

Let $\lambda_1, \lambda_2, \dots, \lambda_n$ be the eigenvalues of A , then

$$\sum_{i=1}^n |\lambda_i|^2 \leq \|A\|_F^2$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 17

So, and there is one more corollary which says that the spectral radius of A , it is less than or equal to a transpose. And if we combine these two A result then we can have this theorem that spectral radius of A is less than or equal to minimum of, maximum of j equal to 1 to n modulus of a_{ij} and maximum of j summation i equal to 1 to n a_{ij} .

So, this is some result which we generally use to look at the information about the Eigenvalue of a given matrix. And there is one more theorem, which says that let λ_1 to λ_n be the Eigenvalues of A then summation i equal to 1 to n modulus of λ_i square less than or equal to Frobenius Norm of A square.

Ah why we are considering all these, is that many a times finding the Eigenvalue is quite difficult and in many application we really need not to find out the exact value of the Eigenvalue, but rather than finding the say bound of the Eigenvalue is sufficient. So, these theorems, these results which we have just illustrated will help you, say giving qualitative information about the matrix A , but without calculating the Eigenvalue of the matrix A .

But now let us consider certain, basic results, basic method to find out all the Eigenvalues of the matrix A . So, this QR method is a very very basic method and it will help you to find out all the Eigenvalue of a given matrix A . And of course, this is a basic method, so it is not applicable for very large matrix or a very same large dimension sparse matrices, because when we calculate very large matrices and it is quite slow and

sometimes your a sparsity may be lost. So, this QR basic method is applicable very well in small size matrices.

So, first let us consider what is QR method and how we can apply this. So, basically QR method applies the real Schur Form matrix form of a given matrix A. So, here we will use the theorem of a real Schur Form of a given matrix A and we consider QR sequence from a given matrix A.

(Refer Slide Time: 24:07)

QR method

QR Method

Given a real $n \times n$ matrix A , define a sequence of $n \times n$ matrices $\{A_k\}$ as follows:

- (a) Set $A_0 = A$
- (b) For $k = 1, 2, \dots, \infty$; calculate A_k as follows:
 - (i) Calculate the Householder QR factorization of A_{k-1}

$$A_{k-1} = Q_{k-1}R_{k-1}$$
 - (ii) Calculate A_k from the relation

$$A_k = R_{k-1}Q_{k-1}$$

 NPTEL ONLINE CERTIFICATION COURSE

18

So, let us consider what is QR method. So, given a real n cross n matrix A define a sequence of n cross n matrices Ak as follows. So, first thing is that you define A naught as the given matrix A and then for k equal to 1 2 to infinity, we can calculate the A 1 A 2 in a form. So, once we have A naught we find out the QR decompo Q QR factorization of A naught.

And once we have Q naught R naught then we can define A 1 as R R naught Q naught or we can say that if for k equal to 4 any arbitrary k. We first calculate the householder QR factorization of Ak minus 1 and let us say that Ak minus 1 is Qk minus 1 into R k minus 1. Then we just reverse the order and we define Ak as R k minus 1 and Qk minus 1 and in this way we can find out the sequence of the matrices Ak.

(Refer Slide Time: 25:04)

Theorem

Let $\{A_k\}$ be the QR method sequence defined as above. Then

$$\text{eig}(A) = \text{eig}(A_k) \text{ for each } k \in \mathbb{Z}_+$$

Proof. We claim that

$$A_k = (Q_0 Q_1 \cdots Q_{k-1})^T A (Q_0 Q_1 \cdots Q_{k-1}) \quad (2)$$

The proof is by induction. We note that

$$A_1 = R_0 Q_0 \text{ and } A_0 = A = Q_0 R_0$$

Since Q_0 is orthogonal, it is invertible so that we have

$$R_0 = Q_0^T A$$

Hence, it follows that

$$A_1 = Q_0^T A Q_0$$

so that Equation (2) holds for $k = 1$.

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 19

Now, once we have this sequence, then how it will help you to find out the Eigenvalue of a given matrices. So, here in for this, this theorem is quite important that let A_k be the eig A_k be the QR method sequence defined as above, then Eigenvalue of the matrix A is nothing, but Eigenvalue of A_k for any k in \mathbb{Z}_+ . So, it means that if you have A_1 you find out the Eigenvalue and it is same as the Eigenvalue of the matrix A . So, spectrum of matrix A is same as the spectrum of A_k .

So, that let us see how it is true. We claim that A_k is nothing, but Q_0 naught to Q_{k-1} transpose A Q_0 naught Q_1 to Q_{k-1} we can. Once we show this thing then Q_0 naught to Q_{k-1} or R_0 or all orthogonal, then this is nothing, but some orthogonal matrix transpose A into orthogonal matrix, and it means that A_k and A are similar matrices and hence a spectrum of A_k and a spectrum of A is same.

So, first let us try to prove this the equation number 2. So, that we are going to prove by induction. So, for k equal to 1 it is quite obvious, because A_1 is basically R_0 naught Q_0 naught and A_0 naught is Q_0 naught R_0 naught. So, using here you can find out the value R_0 naught, R_0 naught is basically Q_0 naught transpose A and when you use the value of R_0 naught in A_1 then A_1 can be written as Q_0 naught transpose A Q_0 naught. So, this two equation is true for k equal to 1 and let us assume for k equal to m .

(Refer Slide Time: 26:45)

Next, suppose that Equation (2) holds for $k = m$, i.e. let

$$A_m = (Q_0 Q_1 \cdots Q_{m-1})^T A (Q_0 Q_1 \cdots Q_{m-1}) \quad (3)$$

Then, by definition,

$$A_{m+1} = R_m Q_m$$

where

$$A_m = Q_m R_m$$

Since Q_m is orthogonal, we have

$$R_m = Q_m^T A_m$$

so that

$$A_{m+1} = Q_m^T A_m Q_m$$

FT ROORKEE

NPTEL ONLINE
CERTIFICATION COURSE

20

So, it means that A_m can be written as $Q_{m-1}^T \cdots Q_0^T A Q_0 \cdots Q_{m-1}$. Then we want to show that it is also true for k equal to $m+1$. So, we already know that the A_{m+1} is defined as $R_m Q_m$ and A_m is given as $Q_m R_m$.

So, with the help of, this $A_m = Q_m R_m$ you can find out the value of R_m , R_m is given as $Q_m^T A_m$. So, using this R_m we can put it here and we can have A_{m+1} as $Q_m Q_m^T A_m Q_m$. Now we can find out the expression for this A_{m+1} which is given in 3.

(Refer Slide Time: 27:23)

Using the induction hypothesis (3), we know that

$$A_{m+1} = Q_m^T(Q_0 Q_1 \cdots Q_{m-1})^T A(Q_0 Q_1 \cdots Q_{m-1}) Q_m$$

i.e.

$$A_{m+1} = (Q_0 Q_1 \cdots Q_{m-1} Q_m)^T A(Q_0 Q_1 \cdots Q_{m-1} Q_m)$$

This completes the induction and hence Equation (2) holds for all values of $k \in \mathbb{Z}_+$. Finally, since a product of orthogonal matrices is orthogonal, it is immediate that the matrix

$$\tilde{Q} = Q_0 Q_1 \cdots Q_{k-1}$$

is orthogonal. Thus, Equation (2) reduces to

$$A_k = \tilde{Q}^T A \tilde{Q}$$

so that A_k is orthogonally similar to A . In particular, the matrices A_k and A have the same eigenvalues. This completes the proof.

FT ROORKEE

NPTEL ONLINE
CERTIFICATION COURSE

21

And we can write it here A_{m+1} as $Q_m^T Q_{m-1}^T \cdots Q_0^T A Q_0 Q_1 \cdots Q_m$. And if we combine this we have A_{m+1} as product of these orthogonal matrices in transpose A into $Q_0^T Q_1^T \cdots Q_m$. So, it means that our relation A_2 holds for all values of k .

Now, as we pointed out that all these $Q_0^T Q_1^T \cdots Q_{k-1}^T$ are all orthogonal matrices and product of orthogonal matrices is orthogonal. So, let us denote this $Q_0^T Q_1^T \cdots Q_{k-1}^T$ as \tilde{Q} and we can write that A_k as $\tilde{Q}^T A \tilde{Q}$. So, we can say that A_k is orthogonally similar to matrix A and we know that orthogonal matrices have the same Eigenvalues.

In fact, they have the same characteristic polynomial. So, they will have the same Eigenvalues and this complete the proof. So, once we have this QR sequence, then I am finding, the Eigenvalue of any particular element will give you the Eigenvalue of the original matrix A .

(Refer Slide Time: 28:34)

Basic QR Method

Let A be a real, $n \times n$ matrix. Assume that the eigenvalues $\lambda_1, \lambda_2, \dots, \lambda_n$ can be ordered so that

$$|\lambda_1| > |\lambda_2| > \dots > |\lambda_n|$$

From the above assumption, it is immediate that all eigenvalues of A are real and distinct. Thus, A is diagonalizable so that A has a set of n linearly independent eigenvectors

$$S = \{x_1, x_2, \dots, x_n\}$$

where $Ax_i = \lambda_i x_i$ for $i = 1, 2, \dots, n$. Form the matrices X and Y where

$$X = [x_1, x_2, \dots, x_n] \text{ and } Y = (X^T)^{-1}$$

Clearly, Y is the matrix of left eigenvectors of A . Assume now that all the leading principle minors of Y are nonzero. Then the sequence $\{A_k\}$ defined in the QR method converges to an upper triangular matrix (its real Schur form).

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 22

So, we need some kind of convergence criteria to work with this basic QR method. So, here is the result which give you the guarantee that, that this process will converge somewhere. So, let A be a real n cross n matrices, assume that the Eigen is λ_1 to λ_n can be ordered in a way that modulus of λ_1 is greater than modulus of λ_2 .

So, we have arranged in a decreasing order. And it is also clear from this arrangement that Eigenvalues of A are real and distinct and once we have Eigenvalue is real and distinct, we can show that the corresponding eigenvectors are also orthogonal to each other and we have n number of linearly independent eigenvectors or we can say that A is diagonalizable and we can write S as x_1 to x_n , where each x is are linearly independent eigenvectors of the matrix A .

And from this set of eigenvectors we can form the capital X which is the matrix of eigenvectors and, we write Y as X transpose inverse and this Y is the matrix of left eigenvectors of A . And assume now that all the leading principle minus of Y are non0, this is one assumption which we are assuming. Then this sequence A_k defined in the QR method converges to an upper triangular matrix which we say that it is its real Schur Form.

So, it means that if we assume these condition, first condition is that it can be arranged in this way, another assumption is that all the leading principle minus of Y are non zero.

Then this sequence A_k will converge to the real Schur Form of the given matrix A . So, basically this is the starting point and we will use this point to find out the Eigenvalues of a given matrix A .

(Refer Slide Time: 30:32)

Remark. We remark that in practice, the calculation involved in the QR method can be further simplified. In fact, under the assumption of the above theorem, it follows that for large values of k , A_k has the form

$$A_k = \begin{bmatrix} \lambda_1 & * \\ 0 & \Gamma \end{bmatrix} \quad (4)$$

where Γ is an $(n-1) \times (n-1)$ matrix.
 Since

$$\text{eig}(A) = \text{eig}(A_k) = \{\lambda_1\} \cup \text{eig}(\Gamma)$$

it is clear that once A_k reduces to the form given in (4), we note down the eigenvalue λ_1 and apply the QR-iteration to Γ .

23

So, here we remarked that in practice the calculation involved in the QR method can be further simplified, and we can say that we when we write A_k as this lambda 1 block matrix, basically lambda 1 0 and something in gamma, where gamma is an n minus 1 cross n minus 1 matrix and we can say that Eigenvalues of A_k is nothing, but this lambda 1 union Eigenvalues of the gamma.

Now, so, now, it is reduced to. Now here this gamma is an n minus 1 cross n minus 1 matrix. So, now, we in n place of a now we start with this gamma matrix, and we say that it is clear that once A_k reduced to the form given in 4, we note down that the Eigenvalue lambda 1 and lamb apply the QR iteration for this matrix gamma and in this way we can calculate all the Eigenvalues of the matrix A .

(Refer Slide Time: 31:29)

It follows again that for large values of k , the QR iteration sequence Γ_k corresponding to Γ has the form

$$\Gamma_k = \begin{bmatrix} \lambda_2 & * \\ 0 & \Omega \end{bmatrix} \quad (5)$$

where Ω is an $(n-2) \times (n-2)$ matrix.
It is clear that this process can be repeated. Thus, we calculate all the n eigenvalues of A . As remarked earlier, once all the eigenvalues $\lambda_1, \lambda_2, \dots, \lambda_n$ are determined, we can then use the inverse iteration algorithm to calculate the associated eigenvectors x_1, x_2, \dots, x_n respectively.

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 24

And it follows again that for large values of k , the QR iteration sequence for γ_k corresponding to γ has this form, γ_k equal to λ_2 0 and non 0 some value and Ω , where Ω is any $n-2$ cross $n-2$ matrix and this process can be repeated. So, that we can find out all the Eigenvalues of the matrix A and.

(Refer Slide Time: 31:54)

Example.

$$A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Eigenvalues of A are 5.3723, and -0.3723, $|\lambda_1| > |\lambda_2|$.
 $k = 0$:

$$A_0 = A = Q_0 R_0$$
$$Q_0 = \begin{pmatrix} -0.3162 & -0.9487 \\ -0.9487 & 0.3162 \end{pmatrix}$$
$$R_0 = \begin{pmatrix} -3.1623 & -4.4272 \\ 0 & -0.6325 \end{pmatrix}$$

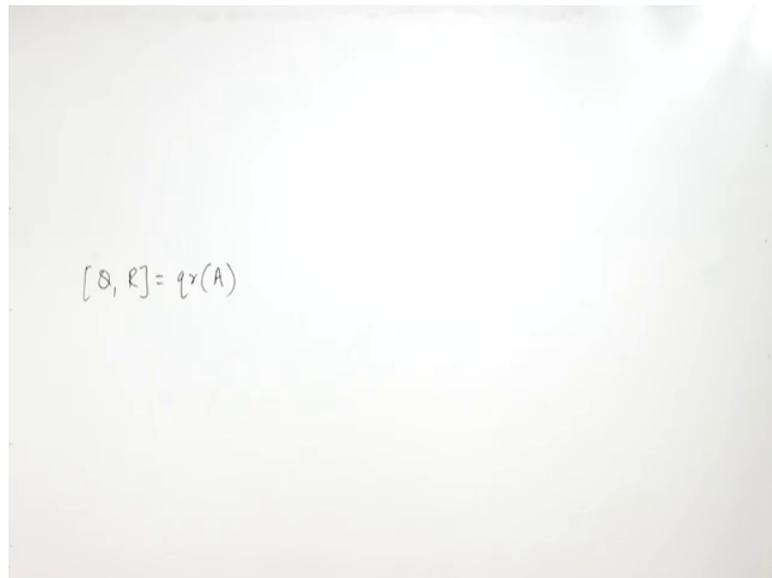

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 25

Once Eigenvalues are given to us then we can use reverse iteration method to find out eigenvectors corresponding the matrix A . Now, let us consider two example based on this basic QR method. So, first is 2 cross 2 matrix. So, A is 1 2 3 4 and we can easily

calculate the Eigenvalues of this matrix A and it is given as 5.3723 and minus 0.3723. And here we can say that modulus of lambda 1 is greater than modulus of lambda 2. So, it is also satisfying the condition of given result.

So, now let us consider the QR sequence. So, A naught is a and we find out Q naught R naught. I hope that you remember the say command for this that is you can write this as this.

(Refer Slide Time: 32:49)

A photograph of a whiteboard with the handwritten equation $[Q, R] = \text{qr}(A)$ written in black marker.

So, here when we write QR is equal to QR of the matrix a. So, that will give you the QR decomposition of a given matrix A. So, it means that given a matrix A you can easily find out Q naught R naught. So, Q naught and R naught is given by this.

(Refer Slide Time: 33:06)

$k = 1 :$

$$A_1 = R_0 Q_0 = \begin{pmatrix} 5.2 & 1.6 \\ 0.6 & -0.2 \end{pmatrix} = Q_1 R_1$$

$$Q_1 = \begin{pmatrix} -0.9934 & -0.1146 \\ -0.1146 & -0.9934 \end{pmatrix}$$

$$R_1 = \begin{pmatrix} -5.2345 & -1.5665 \\ 0 & -0.3821 \end{pmatrix}$$

Then you can find out A_1 as $R_1 Q_1$. So, A_1 is given as $R_1 Q_1$. And once we have A_1 then we can find out the QR decomposition of A_1 , which is given as $Q_1 R_1$ and then we can define A_2 as $R_1 Q_1$, which is given here A_2 as $R_1 Q_1$. So, once we have A_2 , we again find out the QR decomposition and that is $Q_2 R_2$, where Q_2 is given by this and R_2 given by this.

(Refer Slide Time: 33:34)

$k = 2 :$

$$A_2 = R_1 Q_1 = \begin{pmatrix} 5.3796 & -0.9562 \\ 0.0438 & -0.3796 \end{pmatrix} = Q_2 R_2$$

$$Q_2 = \begin{pmatrix} -1 & -0.0082 \\ -0.0081 & 1 \end{pmatrix}$$

$$R_2 = \begin{pmatrix} -5.3797 & 0.9593 \\ 0 & -0.3718 \end{pmatrix}$$

$k = 3 :$

$$A_3 = R_2 Q_2 = \begin{pmatrix} 5.3718 & 1.0030 \\ 0.0030 & -0.3718 \end{pmatrix} = Q_3 R_3$$

$$Q_3 = \begin{pmatrix} -1 & -0.0006 \\ -0.0006 & 1 \end{pmatrix}$$

$$R_3 = \begin{pmatrix} -5.3718 & -1.0028 \\ 0 & -0.3723 \end{pmatrix}$$

Then A_3 we define as $R_2 Q_2$ and it is given by this and once we have this, then again we find out QR decomposition of A_3 , it is given as $Q_3 R_3$, where Q_3 is given by this and R_3 is given by this.

(Refer Slide Time: 33:49)

$k = 4 :$

$$A_4 = R_3 Q_3 = \begin{pmatrix} 5.3723 & -0.9998 \\ 0.0000 & -0.3723 \end{pmatrix}$$

And then we define A_4 as $R_3 Q_3$, and if you look at $R_3 Q_3$ then it is of this form. Here we have a $\lambda = 0$ and whatever some value here and here it is your γ . Now, since we started with the 2×2 matrix and this γ is nothing, but 1×1 matrix. So, here we can say that this A_4 , if you look at this is an upper triangular matrix and Eigenvalue of A_4 is 5.3723 and minus 0.3723.

So, Eigenvalue of A_4 we can easily calculate, and we already know that and that A_k and A will share the same characteristic Eigenvalue. So, the Eigenvalue of A_4 is the same as Eigenvalue of A which we started with here and that we are matching here that Eigenvalue of A is this and that we have achieved here and the fourth iteration. So, A_4 is an upper triangular matrix and we have the Eigenvalues listed here 5.3723 and minus 0.3723.

So, this is an example on QR method sequence, how to find out, how to utilize this QR method sequence to find out the Eigenvalue of the matrix A . Let us consider one more example based on this.

(Refer Slide Time: 35:07)

Example. Let

$$A = \begin{bmatrix} 1 & 2 & 2 \\ 5 & 4 & 6 \\ 2 & 3 & 4 \end{bmatrix}$$

Then the eigenvalues of A are given by

$$\lambda_1 = 9.7764, \lambda_2 = -1.1365 \text{ and } \lambda_3 = 0.3600$$

In this example, we wish to calculate the above eigenvalues using the QR method.

Set $A_0 = A = Q_0 R_0$.

$$Q_0 = \begin{bmatrix} -0.1826 & 0.6300 & -0.7548 \\ -0.9129 & -0.3937 & -0.1078 \\ -0.3651 & 0.6694 & 0.6470 \end{bmatrix} \text{ and } R_0 = \begin{bmatrix} -5.4772 & -5.1121 & -7.3030 \\ 0 & 1.6931 & 1.5750 \\ 0 & 0 & 0.4313 \end{bmatrix}$$

So, now let A is 122546 thru 234. So, this time it is 3 cross 3 matrix and we can find out the Eigenvalue of A as λ_1 is a 9.7764 λ_2 equal to minus 1.1365 and λ_3 as 0.3600.

And now we try to find out eigenvalues using the QR method. So, first thing is A naught as A . Once we have A we can find out say QR decom decomposition using this and we can write Q naught R naught as this, Q naught is given by this matrix and R naught is given by this. Now just reverse the order and we can find out the A_1 matrix. So, A_1 is R naught Q naught.

(Refer Slide Time: 35:50)

k = 1:

$$A_1 = R_0 Q_0 = \begin{bmatrix} 8.3333 & -6.3262 & -0.0394 \\ -2.1207 & 0.3876 & 0.8364 \\ -0.1575 & 0.2887 & 0.2791 \end{bmatrix} = Q_1 R_1$$

$$Q_1 = \begin{bmatrix} -0.9689 & -0.2414 & 0.0535 \\ 0.2466 & -0.9594 & 0.1369 \\ 0.0183 & 0.1458 & 0.9891 \end{bmatrix} \text{ and } R_1 = \begin{bmatrix} -8.6004 & 6.2306 & 0.2495 \\ 0 & 1.1974 & -0.7523 \\ 0 & 0 & 0.3884 \end{bmatrix}$$

Proceeding like this, we get

$$A_7 = \begin{bmatrix} 9.7764 & -4.1672 & -0.4507 \\ -0.0000 & -1.1364 & 0.6567 \\ -0.0000 & 0.0002 & 0.3599 \end{bmatrix} = \begin{bmatrix} \lambda_1 & * \\ 0 & \Gamma \end{bmatrix}$$

30

If you look A naught is Q naught R naught and A_1 is R naught Q naught. So, once we define A_1 then now repeat the same procedure, it means that now find out the QR decomposition of this A_1 . So, let us call this as $Q_1 R_1$. So, once we have $Q_1 R_1$ that is the QR decomposition of the matrix A_1 . So, Q_1 is given by this R_1 is given by this right. And again we reverse order and we define A_2 and in this way we can proceed, and we have seen that in a sense A_7 we have this form.

Now, in A_7 if you look at the first column have only non0 diagonal entry and rest are all 0. So, it is basically this form, λ_1 equal to 0 and λ_1 0 and some non0 and γ . Here γ is this matrix 2 cross 2 matrix. So, here we can see that the one Eigenvalue that is the largest Eigenvalue is given by this λ_1 ; that is 9.7764 and once we have one Eigenvalue with us, now we start working with this γ . So, it means that we have to start working with this γ .

(Refer Slide Time: 37:01)

where Γ is the 2×2 matrix given by

$$\Gamma = \begin{bmatrix} -1.1364 & 0.6567 \\ 0.0002 & 0.3599 \end{bmatrix}$$

Next, we apply QR method to the matrix Γ to determine the remaining two eigenvalues of A , viz λ_2 and λ_3 . $k = 0$:
Set $\Gamma = Q_0 R_0$

$$Q_0 = \begin{bmatrix} -1.0000 & 0.0002 \\ 0.0002 & 1.0000 \end{bmatrix} \text{ and } R_0 = \begin{bmatrix} 1.1364 & -0.6566 \\ 0 & 0.3600 \end{bmatrix}$$

$k = 1$:

$$\Gamma_1 = R_0 Q_0 = \begin{bmatrix} -1.1365 & -0.6565 \\ 0.0001 & 0.3600 \end{bmatrix} = Q_1 R_1$$
$$Q_1 = \begin{bmatrix} -1.0000 & 0.0001 \\ 0.0001 & 1.0000 \end{bmatrix} \text{ and } R_1 = \begin{bmatrix} 1.1365 & 0.6565 \\ 0 & 0.3600 \end{bmatrix}$$

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 31

So, now let us gamma is 2 cross 2 matrix given by the. Now again we repeat the process for this gamma and. So, you assume gamma as Q naught R naught, we can find out the QR decomposition of v gamma and Q naught is given by this and R naught is given by this and we can define gamma 1 as just reverse order; that is R naught Q naught and it is given by this [vocalized-noise. Then find out the QR decomposition of gamma 1 that is Q 1 R 1 and Q 1 is given by this and R 1 is given by this.

(Refer Slide Time: 37:35)

$k = 2$:

$$\Gamma_2 = R_1 Q_1 = \begin{bmatrix} -1.1365 & 0.6565 \\ 0.0000 & 0.3600 \end{bmatrix} = \begin{bmatrix} \lambda_2 & * \\ 0 & \lambda_3 \end{bmatrix}$$

Hence, we have determined all the eigenvalues of A using the QR method.

FT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 32

Then for k equal to 2 γ_2 is equal to $R^{-1}Q^{-1}$, and if you look at $R^{-1}Q^{-1}$ that is γ_2 , it is basically in upper triangular matrix. So, when we have when we have upper triangular matrix we stop and we can see that the Eigenvalue of γ_2 is minus 1.1365 and 0.3600 and we can say that we have determined all the Eigenvalues of A using the QR method.

So, with this we stop. In fact, in this lecture, we have discussed some what is the definition of Eigen pairs and some elementary properties of Eigen pairs I have, we have not discussed any proof of that that we can find out in any good book of linear algebra, and we also discussed the QR, basic QR method to find out the, all the Eigenvalue of the given matrix A . And when we do not require to find out all the Eigenvalues of a given matrix A then we may consider a power method and many more method which we can discuss in coming lectures. So, here we stop thank you for listening us.

Thank you.
