**Lecture - 05**  
**Linear Systems – I**

Hello friends. Welcome to this lecture. In this lecture, we will start our discussion on linear system and its properties, existing uniqueness and some properties related to linear system. So first let us see that the system of differential equations are quite useful and widely used in several areas of science and engineering.

**(Refer Slide Time: 00:49)**

Introduction

Systems of differential equations are quite useful and widely used in several areas of science and engineering.

- Pendulum problems,
- population models,
- mixing problems,
- control problems

are some of the problems which can be studied using system of first order differential equations.

IT ROORKEE    NPTEL ONLINE    CERTIFICATION COURSE    2

And they are some common which we have already discussed that is some problem related to pendulum problem, population models, mixing problem; mixing means we have tank mixing problem, fluid mixing problem, control problems. These are some of the problems which can be studied using system of first-order differential equations.

**(Refer Slide Time: 01:18)**

## Introduction

Consider the following system of first-order differential equations,

$$\begin{aligned}\frac{dx_1}{dt} &= f_1(t, x_1, \dots, x_n), \\ \frac{dx_2}{dt} &= f_2(t, x_1, \dots, x_n), \\ &\vdots \\ \frac{dx_n}{dt} &= f_n(t, x_1, \dots, x_n).\end{aligned}\tag{1}$$

where  $f_i$ ,  $i = 1, 2, \dots, n$  are given functions defined in a region  $D$  of  $(n+1)$ -dimensional Euclidean space and  $x_i(t)$ ,  $i = 1, 2, \dots, n$  are the  $n$  unknown functions of an independent variable  $t$ .

Now in general we can define the first-order differential equation system as follows. So consider the following system of first-order differential equation,  $dx_1/dt=f_1 t, x_1$  to  $x_n$ ,  $dx_2/dt=f_2 t, x_1$  to  $x_n$  and so on  $dx_n/dt=f_n t, x_1, x_n$  here. Now here these  $f_i$ 's are  $i=1$  to  $n$  are given functions defined in a region  $D$  of  $n+1$  dimensional Euclidean space and these  $x_i t, i$  from 1 to  $n$  are the  $n$  unknown functions of an independent variable  $t$ .

So our aim is like to find out these  $x_i$ 's such that it satisfy the equation number 1 for given  $f_1$ ,  $f_2$  and  $f_n$ .

**(Refer Slide Time: 02:18)**

## Introduction

Along with the ordinary differential equation we often have conditions to be satisfied by the solution at a fixed point  $t = t_0$  given as follows

$$x_1(t_0) = x_1^0, x_2(t_0) = x_2^0, \dots, x_n(t_0) = x_n^0.\tag{2}$$

Equation (1) together with the initial conditions (2), is known as an initial-value problem.

A solution of the initial-value problem is a solution  $x_1(t), \dots, x_n(t)$  of (1) satisfying the initial conditions (2).

So most of the time along with the ordinary differential equation, we often have conditions to be satisfied by the solution at a fixed point say  $t=t_0$  and which can be written like this that  $x_1 t_0 = x_1^0$ ,  $x_2 t_0 = x_2^0$  and so on  $x_n t_0 = x_n^0$ . So equation 1 means the differential equation 1

along with the conditions which is defined at  $t=t_0$  generally called as initial conditions. So equation 1 together with the initial condition 2 is known as an initial-value problem.

And in a ((03:03)) language a solution of the initial-value problem is the solution  $x_1$  to  $x_n$   $t$  of 1 satisfying the initial condition 2. So it means that roughly I can say that the solution of the initial-value problem is  $n$  unknowns  $x_1$  to  $x_n$  says that it satisfy the equation number 1 along with the condition given in 2 that is  $x_1(t_0)=x_1(0)$ ,  $x_2(t_0)=x_2(0)$  and so on.

**(Refer Slide Time: 03:31)**

**Example 1**  
 Consider the following system of linear differential equations:

$$\begin{cases} \frac{dx_1(t)}{dt} = x_1 + x_2, & x_1(0) = 1 \\ \frac{dx_2(t)}{dt} = x_2, & x_2(0) = 1. \end{cases}$$

and verify that  $x_1(t) = e^t(1+t)$  and  $x_2(t) = e^t$  forms a solution set of the initial-value problem

*Handwritten notes:*  
 $f_1(t, x_1, x_2) = x_1 + x_2$   
 $f_2(t, x_1, x_2) = x_2$   
 $x_1' = f_1(t, x_1, x_2)$   
 $x_2' = f_2(t, x_1, x_2)$   
 $x_2(t) = k e^t$   
 $x_2(0) = 1 \Rightarrow k = 1$   
 $x_2(t) = e^t$   
 $x_1'(t) = x_1 + e^t, x_1(0) = 1$   
 $\frac{d}{dt} (e^{-t} x_1(t)) = 1 \Rightarrow e^{-t} x_1(t) = t + C$   
 $1 = C$   
 $x_1(t) = e^t(1+t)$   
 $x_1(0) = 1, x_2(0) = 1$

So now let us consider some example to which we try to understand the concept of system of differential equations. So consider the following system of linear differential equations,  $dx_1/dt=x_1+x_2$ ,  $x_1(0)=1$  and  $dx_2/dt=x_2$ ,  $x_2(0)=1$  here. So here it is similar to your problem  $x_1$  dash=f t,  $x_1$ ,  $x_2$  and  $x_2$  dash=f t sorry  $f_1$  and  $f_2$   $x_1$  and  $x_2$ . So here your  $f_1$  of  $t$ ,  $x_1$  and  $x_2$  is given by  $x_1+x_2$  and  $f_2$   $t$ ,  $x_1$  and  $x_2$  is given by say  $x_2$  here.

An initial condition is given at the point 0 that is  $x_1(0)=1$  and  $x_2(0)=1$ . Now here if you look at this system is defined and if you look at the second system that  $dx_2/dt$  is  $=x_2$ , so it means that the function  $f_2$  is not depending on the variable  $x_1$  and so we can easily solve this system this linear equation  $dx_2/dt=x_2$  provided that  $x_2(0)=1$  and you can find out that  $x_2(t)$  is  $=$ constant times  $e$  to power  $t$  and the condition  $x_2(0)=1$  will fix the value  $k$  and it is given as  $e$  to power  $t$ .

So  $x_2(t)$  is given as  $e$  to power  $t$  and once your  $x_2(t)$  is given to you, you can use the first equation that is  $dx_1/dt=x_1+x_2$  and you can find out the value of  $x_1$  also. So here we can say that  $x_1$  dash  $t$  is  $=x_1+x_2$  is given as  $e^t$  and  $x_1(0)=1$ . If you look at this is nothing but a linear

differential equation, scalar linear differential equation and you can simply that is you can write it  $d/dt$  as  $e^{-t}$  times  $t$  is  $=1$ .

What you can do? You just multiply by  $e^{-t}$  which is the integrating factor of this part  $x_1 e^{-t}$  and we can simplify and we can write this as  $e^{-t}$  times  $t + \text{some constant}$  let us say call  $c$  and the condition is given that  $x_1(0) = 1$  if you use the condition then it is nothing but  $1 = c$ , so it means that  $c$  is fixed now. So we can simplify this and we can write down that  $x_1 = e^t$  and  $x_2 = e^{-t}$  is the solution of this system of linear differential equation.

So here we can say that the given system of linear differential equation is having a solution  $x_1 = e^t$  and  $x_2 = e^{-t}$  and we can call these as that  $x_1$  and  $x_2$  forms a solution set of the initial-value problem given as this.

**(Refer Slide Time: 06:42)**

**Example 2**

Consider an initial value problem of the following form

$$\frac{d^n y}{dt^n} = f(t, y, y', \dots, y^{(n-1)});$$

$$y(t_0) = y_0, y'(t_0) = y_1, \dots, y^{(n)}(t_0) = y_{n-1}.$$

Find a system of first order differential equation for the above  $n$ th-order differential equation.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

Now coming to example number 2 which is very important in the sense that it gives you the way that any differential equation of  $n$ th order can be reduced to a system of first-order differential equation. So here the differential equation is given as this, the  $d^n y / dt^n = f(t, y, y'$  up to  $y^{(n-1)}$  along with the initial condition that is  $y(t_0) = y_0, y_1$  dash  $t_0 = y_1$  and  $y_n(t_0) = y_{n-1}$ . So this is the  $n$ th order differential equation and we want to convert this to a system of first-order differential equation and let us see how we can do this.

**(Refer Slide Time: 07:32)**

$x_2(t) = \frac{dy}{dt} = \frac{d}{dt} \left( \frac{dy}{dt} \right) = x_2'(t)$

Set  $x_1(t) = y, x_2(t) = \frac{dy}{dt}, \dots, x_n(t) = \frac{d^{n-1}y}{dt^{n-1}}$ . Then,

$$\frac{dx_1}{dt} = x_2, \frac{dx_2}{dt} = x_3, \dots, \frac{dx_n}{dt} = f(t, x_1, x_2, \dots, x_n).$$

Moreover, the functions  $x_1, x_2, \dots, x_n$  satisfy the initial conditions

$$x_1(0) = y_0, x_2(0) = y_1, \dots, x_n(0) = y_{n-1}.$$

$\Rightarrow \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} y_0 \\ y_1 \\ \vdots \\ f(t, x_1, x_2, \dots, x_n) \end{pmatrix}$

$x_1(t_0) = y_0$   
 $x_2(t_0) = y_1$   
 $\vdots$   
 $x_n(t_0) = y_{n-1}$

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 7

So for converting it let us assume some n variables and these n variables we can say that we can identify that this is nth order differential equation, so we have to choose n number of variables and let us choose n number of variables like  $x_1 t=y, x_2 t=dy/dt$  and  $x_n t=d^{n-1}/dt^{n-1}$ . Now using the definition of these variables, we can simplify that  $x_1 t$  is  $y_1$  and  $x_2 t=dy/dt$ , so if you combine this we can say that  $x_2 t$  is  $dx_1/dt$ .

So first differential equation we can write it as  $dx_1/dt=x_2$  and similarly we can look at  $x_3 t, x_3 t$  is  $d^2y/dt^2$  and we can simply say that this is nothing but  $d/dt$  of  $dy/dt$  and  $dy/dt$  is  $x_2$ , so we can say that your  $x_3$  is  $x_2$  dash  $t$ . So we can write  $dx_2/dt=x_3$  and so on in this way we can say that  $dx_n/dt$  is  $f t, x_1, x_2$  and so on. So it means that here we can write down our equation like  $x_1$  dash,  $x_2$  dash up to  $x_n$  dash.

And this I can write it here as say  $x_2, x_3$  and so on up to  $f t, x_1, x_2$  and so on. So it means that this is the differential equation system of a sort of differential equation.

**(Refer Slide Time: 09:11)**

### Example 2

Consider an initial value problem of the following form

$$\frac{d^n y}{dt^n} = f(t, y, y', \dots, y^{(n-1)});$$

$$y(t_0) = y_0, y'(t_0) = y_1, \dots, y^{(n)}(t_0) = y_{n-1}.$$

Find a system of first order differential equation for the above nth-order differential equation.

$$x_1(t) = y(t)$$

$$x_2(t) = y'(t)$$

$$x_3(t) = y''(t)$$

$$\vdots$$

$$x_n(t) = y^{(n-1)}(t)$$

And initial condition also we can find out, so initial conditions are given as  $y(t_0)=y_0$ ,  $y'(t_0)=y_1$  and  $y^{(n)}(t_0)=y_{n-1}$ . So since we have assumed that  $x_1(t)=y(t)$ , so we can say that  $x_1(t_0)=y_0$ . Similarly, we can say that  $x_2(t_0)=y_1$  and so on  $x_n(t_0)=y_{n-1}$ . So it means that along with the system of differential equation, we can get our initial condition as  $x_1(t_0)=y_0$  and  $x_2(t_0)=y_1$  and up to  $x_n(t_0)=y_{n-1}$ .

So this is the system of differential equation along with the initial condition defined like this. So it means that this example gives us the idea that every nth order differential equation, ordinary differential equation can be reduced to a system of first-order differential equation in this way in the way which we have just discussed.

**(Refer Slide Time: 10:17)**

### Example 3

Consider the system

$$\begin{cases} x_1' = x_1 - tx_2 + e^t \\ x_2' = t^2 x_1 - x_3 \\ x_3' = x_1 + x_2 - x_3 + 2e^{-t} \end{cases} \quad (3)$$

which is linear in  $x_1, x_2$ , and  $x_3$ .

Consider  $x' = f(t, x)$  with  $x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$ ,  $f(t, x) = \begin{pmatrix} x_1 - tx_2 \\ t^2 x_1 - x_3 \\ x_1 + x_2 - x_3 \end{pmatrix} + \begin{pmatrix} e^t \\ 0 \\ 2e^{-t} \end{pmatrix}$

Now moving onto example 3 and here we consider the system  $\dot{x}_1 = x_1 - tx_2 + e$  to power  $t$ ,  $\dot{x}_2 = t^2 x_1 - x_3$  and  $\dot{x}_3 = x_1 + x_2 - x_3 + 2e$  to power  $-t$ . Now we want to form the system of first-order differential equation from this and here we can say that each system here this is linear in terms of  $x_1$ ,  $x_2$  and  $x_3$ . So we can form this equation number 3 as follows,  $\dot{x} = f(t, x)$ , we can look at the equation number 3 as  $\dot{x} = f(t, x)$  where  $x$  is defined as a vector  $x_1, x_2, x_3$ .

And  $f(t, x)$  we can define as  $x_1 - tx_2$  to power  $t$ ,  $t^2 x_1 - x_3$  to power  $t$ ,  $x_1 + x_2 - x_3 + 2e$  to power  $-t$ . So it means that we can write this equation number 3 as  $\dot{x} = f(t, x)$  where  $x$  is a vector given like this and  $f(t, x)$  is a vector given like this.

**(Refer Slide Time: 11:22)**

Then the vector  $\begin{pmatrix} x_1 - tx_2 \\ t^2 x_1 - x_3 \\ x_1 + x_2 - x_3 \end{pmatrix}$  can be represented as the matrix vector product  $A(t)x$  with

$$A(t) = \begin{pmatrix} 1 & -t & 0 \\ t^2 & 0 & -1 \\ 1 & 1 & -1 \end{pmatrix} \text{ and } x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$$

and  $x$  regarded as a column vector.

The slide includes a blue header bar at the top, a blue footer bar with the IIT Roorkee logo and 'NPTEL ONLINE CERTIFICATION COURSE' text, and a small number '9' in the bottom right corner.

So it means that this vector the vector given here can be further simplified and you can write down this vector  $x_1 - tx_2$  to power  $t$ ,  $t^2 x_1 - x_3$  and  $x_1 + x_2 - x_3$  as  $A(t)x$  where  $A(t)$  is given as  $1, -t, 0; t^2, 0, -1; 1, 1, -1$  and  $x$  is given like this.

**(Refer Slide Time: 11:48)**

### Example 3

Consider the system

$$\begin{cases} x_1' = x_1 - tx_2 + e^t \\ x_2' = t^2x_1 - x_3 \\ x_3' = x_1 + x_2 - x_3 + 2e^{-t} \end{cases} \quad \text{where } x' = A(t)x + f(t) \quad (3)$$

which is linear in  $x_1, x_2,$  and  $x_3$ .

$$\text{Consider } x' = f(t, x) \text{ with } x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}, f(t, x) = \begin{pmatrix} x_1 - tx_2 \\ t^2x_1 - x_3 \\ x_1 + x_2 - x_3 \end{pmatrix} + \begin{pmatrix} e^t \\ 0 \\ 2e^{-t} \end{pmatrix}$$

So it means that this system I can write out equation number 3, I can write down this as  $x' = Ax + f(t)$  like this where  $f(t)$  is given by  $e^t, 0, 2e^{-t}$ . So it means that the system given as equation number 3 can be reduced to  $x' = Ax + f(t)$  where  $f(t)$  is given like this and  $A(t)$  is defined as follows and here your  $x$  is regarded as column vector.

**(Refer Slide Time: 12:27)**

Hence, the system (3) can be considered as  $x' = A(t)x + g(t)$ , where  $g(t)$  is a given vector  $\begin{pmatrix} e^t \\ 0 \\ 2e^{-t} \end{pmatrix}$ , also regarded as column vector.

$f, g(t) \in \mathbb{R}^{3 \times 1}$

And the system 3 as we have pointed out is written as  $x' = Ax + g(t)$  where  $g(t)$  is a given vector  $e^t, 0, 2e^{-t}$  and it is also regarded as a column vector. Now if you look at  $g(t)$  is what basically, here  $g(t)$  is a vector-valued function, so it means what, that for each  $t$  this  $e^t$  gives you a real value and  $2e^{-t}$  gives you a real value. So it means that for each  $t$   $g(t)$  belongs to  $\mathbb{R}^3 \times 1$ . So it means that for each  $t$ ,  $g(t)$  gives you a vector in  $3 \times 1$ , so  $g(t)$  gives you a  $3 \times 1$  vector for each  $t$ .

**(Refer Slide Time: 13:17)**

A vector-valued function  $g = g(t)$  is a relation that assigns each number  $t$  in an interval  $I$  to a unique vector  $g(t)$ ; and denote

$$g(t) = \begin{pmatrix} g_1(t) \\ g_2(t) \\ \vdots \\ g_n(t) \end{pmatrix}$$

$x \in I$   
 $\hookrightarrow g: I \rightarrow \mathbb{R}^{n \times 1}$   
 $t \rightarrow g(t) = \begin{pmatrix} g_1(t) \\ g_2(t) \\ \vdots \\ g_n(t) \end{pmatrix}$

and we call  $g_k$ , the  $k$ th component of the vector function  $g$  and we may now define  $g$  to be continuous, differentiable or integrable on  $I$  if each component of  $g$  has the said property. If  $g$  is differentiable on  $I$ , we denote its derivative by  $g'$  and we write

$$g' = \begin{pmatrix} g'_1(t) \\ g'_2(t) \\ \vdots \\ g'_n(t) \end{pmatrix}$$

So in general we can define like this. A vector-valued function  $g=g(t)$  is a relation that assign each number  $t$  in an interval  $I$  to a unique vector  $g(t)$ . So it means that it is a map from say an interval which belongs to so  $t$  belongs to  $I$ , so it means  $I$  can write  $g$  as from  $I$  to say  $\mathbb{R}^n \times 1$  here. So for given  $t$ , you can map to  $g(t)$  which is denoted as  $g_1(t)$ ,  $g_2(t)$  and so on  $g_n(t)$ .

So basically here vector-valued function  $g$  is defined as a map which is a map defined from  $I$  to  $\mathbb{R}^n \times 1$ , for given any  $t$  it gives you a vector defined as  $g(t)$  like  $g_1(t)$ ,  $g_2(t)$  and  $g_n(t)$  and we call like its components are the  $k$ th component of the vector function  $g$  and we may define the continuity of these vector-valued function continuity, differentiability and integrability of these vector-valued function in terms of its component.

So we can say that  $g$  is continuous, differentiable or integrable on an interval  $I$  if each component of  $g$  means  $g_1(t)$ ,  $g_2(t)$ , and  $g_n(t)$  has the said property. It means that if  $g$  is said to be continuous, if each component is continuous,  $g$  is said to be differentiable. If each component is differentiable,  $g$  is said to be integral if each component is integrable. Now we can define if  $g$  is differentiable, we can denote the derivative of  $g$  by  $g'$  and it can be given as  $g'_1(t)$ ,  $g'_2(t)$  and  $g'_n(t)$ .

So it means that the property continuity, differentiability and integrability is given in terms of component and we can find out the derivative of vector-valued function  $g$  in terms of its component and it is given by this that  $g' = g'_1(t)$ ,  $g'_2(t)$  up to  $g'_n(t)$ .

**(Refer Slide Time: 15:32)**

Similarly, if  $g$  is continuous on  $I$ , then we denote its integral from  $a$  to  $b$  by  $\int_a^b g(s) ds$  and we define

$$\int_a^b g(s) ds = \left( \int_a^b g_1(s) ds, \int_a^b g_2(s) ds, \dots, \int_a^b g_n(s) ds \right)^T$$

We take note of the very important inequality

$$\left| \int_a^b g(s) ds \right| \leq \int_a^b |g(s)| ds$$

*norm*

$$\int_a^b g(s) ds = \begin{pmatrix} \int_a^b g_1(s) ds \\ \vdots \\ \int_a^b g_n(s) ds \end{pmatrix}$$

And in a similar way, we can define that if  $g$  is continuous on interval  $I$ , then we denote its integral from  $a$  to  $b$  by  $\int_a^b g(s) ds$  and we can define  $\int_a^b g(s) ds$  as basically it is also a vector. In the first component, it is  $\int_a^b g_1(s) ds$ ,  $\int_a^b g_2(s) ds$  and  $\int_a^b g_n(s) ds$ . So it means that integral of  $g$  of  $s$   $ds$  is basically an integral of its each component. That is how we define the integral of a vector-valued function.

And most of the time, we use this kind of important inequality that is norm of  $\int_a^b g(s) ds$  is  $\leq \int_a^b \text{norm of } g(s) ds$ . Now here this represent the norm of a vector-valued function and here in this we will talk about this norm little bit later and we will see what kind of function is defined as a norm of the function.

**(Refer Slide Time: 16:45)**

To prove (4) we have, successively

$$\left| \int_a^b g(s) ds \right| = \left| \int_a^b g_1(s) ds + \dots + \int_a^b g_n(s) ds \right| \rightarrow \sqrt{\left( \int_a^b g_1(s) ds \right)^2 + \dots + \left( \int_a^b g_n(s) ds \right)^2}$$

$$\leq \int_a^b |g_1(s)| ds + \dots + \int_a^b |g_n(s)| ds = \int_a^b |g(s)| ds.$$

(Here we define  $\|y\| = \sum_{i=1}^n |y_i|$  as absolute sum of its component.)

$$\|z\| = \sum_{i=1}^n |z_i|$$

$$z_i = a_i + ib_i$$

$$|z_i| = \sqrt{a_i^2 + b_i^2}$$

Now to prove this inequality, we can simply write the norm of  $\int_a^b g_i ds$  and here norm we are taking like this that norm of  $y$  is nothing but absolute sum of its component that is norm of  $y$  is given as  $\sum_{i=1}^n \text{modulus of } y_i$ . Now here it is simply modulus and here this represents the norm of  $y$  and to differentiate between the modulus and norm many at times we use this notation that is like this.

So here when we consider the vector-valued function this is denoting, this denotes the norm of vector-valued function and when we talk about the component then this represent the modulus of or absolute value of its component. So we can define norm of  $\int_a^b g_i ds = \sum_{i=1}^n \int_a^b |g_i| ds$  as we have already defined that a norm is given at the absolute sum of its component. So we can write down the modulus of  $\int_a^b g_1 ds + \text{modulus of } \int_a^b g_2 ds + \text{so on modulus of } \int_a^b g_n ds$ .

Now this can be written as this can be bounded by  $\leq \int_a^b \text{modulus of } g_1 ds$  and similarly this can be this is bounded by  $\int_a^b \text{modulus of } g_n ds$ . Now if we can simply write this as  $\int_a^b |g_1 + g_2 + \dots + g_n| ds$  and if you look at this is nothing but norm of  $g$ . So we can write this  $\int_a^b \text{norm of } g ds$ . So I can write it like this. So here to prove this inequality, we are using the following definition of norm that norm of  $y$  is  $\sum_{i=1}^n \text{modulus of } y_i$  right.

Now here I am assuming that  $y_i$ 's are real-valued function. Now if it is complex-valued function then this modulus is supposed to be the modulus of  $y_i$ . That is here if  $y_i$  are complex, then I can write this as  $a_i + ib_i$  then modulus of  $y_i$  is nothing but the under root  $a_i^2 + b_i^2$ . So here right now I am assuming that  $y_i$  is a real-valued function that is why I am calling it as modulus function.

Otherwise it will give you the absolute values. So in case of complex, I can consider this modulus of  $y_i$  as under root  $a_i^2 + b_i^2$ . So it means that this property is very useful and will use in a later slides.

**(Refer Slide Time: 19:45)**

## Solution of the linear system

Consider again the system

$$\dot{x} = f(t, x) \quad (5)$$

$x = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \in \mathbb{R}^{n \times 1}$

where the vector-valued function  $f$  is defined in some  $(n + 1)$ -dimensional region  $D$  in  $(t, x_1, x_2, \dots, x_n)$  space.

To find a solution of (5), we need to find a real interval  $I$  and a vector function  $x$  defined on  $I$  such that:

- (i)  $\dot{x}(t)$  exists for each  $t$  on  $I$ ;
  - (ii) the point  $(t, x(t))$  lies in  $D$  for each  $t$  on  $I$ ;
  - (iii)  $\dot{x}(t) = f(t, x(t))$  for every  $t$  on  $I$ .
- $t, (t, x(t)) \in D$   
 $\eta \in \mathbb{R}^{n \times 1}$

To solve an initial value problem for the system (5) with the initial condition  $x(t_0) = \eta$ , where  $(t_0, \eta)$  is a point in  $D$ , we need to find a solution  $x$  of (5) passing through the point  $(t_0, \eta)$  of  $D$ , that is, satisfying  $x(t_0) = \eta$ .

Now we define what we mean by solution of the system. So for that we consider the system  $\dot{x} = f(t, x)$  where the vector-valued function  $f$  is defined in some  $n+1$  dimensional region  $D$  in  $t, x_1, x_2, \dots, x_n$  space and we try to define what do you mean by the solution of the system in 5. So here we define what we mean by solution of the system. For that we consider the system  $\dot{x} = f(t, x)$ .

Here  $x$  is  $x_1$  to  $x_n$  and it is a vector in  $\mathbb{R}^n \times 1$  and  $f$  is a function vector-valued function defined in  $n+1$  dimension region  $D$  in  $t, x_1, x_2, \dots, x_n$  space. Now what you mean by solution of the system? To find out a solution of the system 5, we need to find out a real interval  $I$ . First of all, we need to find out an interval  $I$  in which this vector function  $x$  is defined and defined in a way such that  $\dot{x}$  exists for each  $t$  in  $I$ .

Second the point  $t, x(t)$  lies in domain  $D$  where we are talking all these things for each  $t$  on  $I$ . So for each  $t$  the tuple  $t, x(t)$  will lie in domain  $D$ . Third, that  $\dot{x} = f(t, x(t))$  is satisfied. So first thing is that derivative exists for all  $t$  in that interval. Second for each  $t$  your  $t, x(t)$  will lie in your domain and third is that derivative exists and it is equal to the value of  $f(t, x(t))$  for every  $t$  on this interval  $I$ .

If it is happening, we call the vector-valued function  $x$  as a solution of the system 5 and to solve an initial value problem for the system with initial condition  $x(t_0) = \eta$ . So if along with this equation number 5 if we have initial condition given as  $x(t_0) = \eta$ , here  $\eta$  is also a vector in  $\mathbb{R}^n \times 1$ . So  $\eta$  is also a vector of size  $n \times 1$  and we want to find out a solution of  $\dot{x} = f(t, x)$  with the initial condition that  $x(t_0) = \eta$  where  $t_0$  and  $\eta$  is a point in domain  $D$ .

We need to find out a solution  $x$  of 5 means this system passing through the point  $t_0, \eta$  of  $D$  that is  $x$  of  $t_0$  is  $\eta$ . So solution of the system is having these 3 properties and solution of the initial-value problem is in additional property that  $x$  of  $t_0$  is  $\eta$ , it means that it is passing through the point  $t_0, \eta$ .

(Refer Slide Time: 22:58)

$x' = f(t, x)$

**Theorem 1**

Let  $f$  be a vector function (with  $n$  components) defined in a region  $D$  of  $(n + 1)$ -dimensional Euclidean space. Let the vectors  $f, \frac{\partial f}{\partial x_k}$ , ( $k = 1, 2, \dots, n$ ) be continuous in  $D$ . Then given any point  $(t_0, \eta)$  in  $D$ , there exists a unique solution  $x$  of the system

$$x' = f(t, x) \quad (6)$$

satisfying the initial condition  $x(t_0) = \eta$ . The solution  $x$  exists on any interval  $I$  containing  $t_0$  for which the point  $(t, x(t))$ , with  $t$  in  $I$ , lie in  $D$ . Furthermore, the solution  $x$  is a continuous function of  $(t, t_0, \eta)$ .

If the region  $D$  is the entire  $(t, x)$  space, then from above theorem, it follows that every solution exists as long as its norm remains finite.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 15

Now for once we know the notation of solution what do you mean by solution, then our first thing to consider is the existence of solution, so as you remember that we have discussed the existence and uniqueness theorem in a scalar-valued case that is when we have  $x' = f(t, x)$  where  $x$  is a scalar-valued function. Now in a similar way, we can define the existence and uniqueness theorem for vector-valued function also.

So let us consider the following theorem. Let  $f$  be a vector function with  $n$  components defined in a region  $D$  of  $n+1$  dimensional Euclidean space and let the vector  $f$  and  $\frac{df}{dx_k}$  where  $k$  is running from 1 to  $n$  be continuous in a domain  $D$ . So first thing is that we have a vector-valued function  $f$  which is defined in a region  $D$  of  $n+1$  dimensional Euclidean space and assume that  $f$  and its partial derivative up to  $n$ th order are continuous in that domain  $D$ .

Then, given any point  $t_0, \eta$  in  $D$  there exists a unique solution  $x$  of the system  $x' = f(t, x)$  which satisfy the initial condition  $x(t_0) = \eta$  and the solution  $x$  exists on any interval  $I$  containing  $t_0$  for which the point  $t, x(t)$  with  $t$  in  $I$  lie in  $D$  and if you remember in scalar-valued function, this theorem is the local existence theorem. So it means that here the solution will define in a small neighborhood of  $t_0, \eta$ .

So that is why we are saying that solution will exist in an interval  $I$  containing  $t_0$  for which this point  $t$ ,  $x(t)$  where  $t$  is in  $I$  lie in domain  $D$ . Furthermore, the solution  $x$  which we obtain is a continuous solution corresponding to  $t$ . So it means that first thing is that solution exists in a neighborhood around  $t_0$  and the obtained solution is a continuous function satisfying the equation number 6.

Now if this domain  $D$  which we are talking about is the entire  $t, x$  space then from this theorem, we can say that it follows that every solution exists as long as its norm remains finite. So it means that if this we are talking about this domain right now, now if this domain  $D$  happens to be the entire space, then for any point we can find out a domain  $D$  and our solution exists in the interval  $I$  for which the point  $t$  and  $x(t)$  is lying in the domain  $D$ .

Now if  $D$  is the entire space, then we can say that the solution exists using the theorem 1 as long as the norm of that solution remains finite right. So it means that this solution will exist for all  $t$  for which the solution is a bounded solution. So this gives you that if region  $D$  or domain  $D$  is the entire space, then we have to look at the region in which your solution is bounded, solution is bounded means the norm of the solution is bounded.

And we say that solution exists for all  $t$  for which your norm of  $x(t)$  is bounded. So let us consider example based on whatever we have discussed. So consider the example 2.

**(Refer Slide Time: 26:58)**

*$x' = f(t, x)$*

**Example 2**

Consider the scalar differential equation  $x' = \alpha x$  for some constant  $\alpha$ . Here  $f(t, x) = \alpha x$  and  $\frac{\partial f}{\partial x}(t, x) = \alpha$ .

Both  $f$  and  $\frac{\partial f}{\partial x}$  are continuous in the whole  $(t, x)$  plane. So, by the above theorem, there is a unique solution  $\phi$  of  $x' = \alpha x$  through every point  $(t_0, x_0)$  in the plane. It is easily verified that

$$\phi(t) = x_0 \exp[\alpha(t - t_0)]$$

is a solution of this initial value problem.

*$x' = \alpha x$   
 $x(t_0) = x_0$*

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 16

Say consider the scalar-valued function a scalar differential function  $x' = \alpha x$  for some constant  $\alpha$  and here we can check that  $f(t, x)$  is  $\alpha x$  and  $\frac{df}{dx}$  is  $\alpha$ . So it means that here  $x' = f(t, x)$  and this  $f$  is continuous because it is  $\alpha x$ , it is continuous for all  $x$  and the derivative of  $f$  with respect to  $x$  which is given as  $\alpha$ ,  $\alpha$  is a constant value, so it is also continuous for all for the entire space.

So here we can say that both  $f$  and  $\frac{df}{dx}$  are continuous in the whole  $t, x$  space. So by the above theorem, there is a unique solution  $\phi$  of  $x' = \alpha x$  through every point  $(t_0, x_0)$  in the plane. So it means that given any point  $(t_0, x_0)$ , the solution of this problem  $x' = \alpha x$  and  $x(t_0) = x_0$ . So it means that for every initial condition, solution of this problem exists.

Now we can also verify that your solution  $\phi(t)$  is given as  $x_0 \exp(\alpha(t - t_0))$ . That is not very difficult to obtain. You can find out the solution using separation and variable method and we can say that this is one solution of the initial-value problem and since it satisfy the condition of the existence and uniqueness theorem. So we say that this is the solution of the initial-value problem.

**(Refer Slide Time: 28:31)**

Therefore,  $\phi(t) = x_0 \exp[\alpha(t - t_0)]$  is the only solution.

Also, since  $|\phi(t)| = |x_0| \exp[\alpha(t - t_0)]$  is finite for all finite  $t$ ,  $(t, \phi(t))$ ,  $-\infty < t < \infty$ , lie in  $D$  and therefore this solution  $\phi$  exists for  $-\infty < t < \infty$ .

NPTEL ONLINE  
CERTIFICATION COURSE  
17

Therefore, we can say that  $\phi(t) = x_0 \exp(\alpha(t - t_0))$  is the only solution which we are discussing. Now we say that we can find out the modulus value of  $\phi(t)$  and you can check that it is given as modulus of  $x_0 \exp(\alpha(t - t_0))$  and if you look at this is always finite for all finite  $t$  such that  $(t, \phi(t))$  belongs to the  $t, x$  space and here  $t$  is lying between  $-\infty$  to  $\infty$ .

So it means that this solution  $\phi$  exists for all  $t$  between  $-\infty$  to  $\infty$ . So here since this condition that  $f$  and partial derivative of  $f$  exists for all  $t, x$ , so we can say that solution will exist for all  $t, x$  for which norm of  $\phi(t)$  is bounded and you can see that here the norm of  $\phi(t)$  is always bounded for all finite  $t$ . So it means that solution of this problem exists for all  $t$ .

(Refer Slide Time: 29:51)

Example 3

Discuss the problem of existence and uniqueness of solutions of the initial value problem for the system

$$\begin{aligned} \dot{x}_1 &= tx_2 + x_3 \\ \dot{x}_2 &= (\cos t)x_1 + t^2x_3 \\ \dot{x}_3 &= x_1 - x_2 \end{aligned}$$

This system is of the form  $\dot{x}' = f(t, x)$  with  $x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$ ,

$$f(t, x) = \begin{pmatrix} tx_2 + x_3 \\ \cos tx_1 + t^2x_3 \\ x_1 - x_2 \end{pmatrix}.$$

18

Now looking at next example and here also we want to discuss the problem of existence and uniqueness and consider the system  $\dot{x}_1 = tx_2 + x_3$ ,  $\dot{x}_2 = \cos tx_1 + t^2x_3$ ,  $\dot{x}_3 = x_1 - x_2$  and we can write down this system as  $\dot{x} = f(t, x)$  with  $x = x_1, x_2, x_3$  and  $f(t, x)$  is  $tx_2 + x_3, \cos tx_1 + t^2x_3$  and  $x_1 - x_2$ .

(Refer Slide Time: 30:16)

Hence  $f(t, x)$  is continuous for  $|t| < \infty, |x| < \infty$ .

Moreover,

$$\frac{\partial f}{\partial x_1} = \begin{pmatrix} 0 \\ \cos t \\ 1 \end{pmatrix}, \frac{\partial f}{\partial x_2} = \begin{pmatrix} t \\ 0 \\ -1 \end{pmatrix}, \frac{\partial f}{\partial x_3} = \begin{pmatrix} 1 \\ t^2 \\ 0 \end{pmatrix},$$

which are also continuous for  $|t| < \infty, |x| < \infty$ . Thus  $D$  is all of four-dimensional  $(t, x_1, x_2, x_3)^T$  space and through any point  $(t_0, \eta)$  there passes a unique solution  $\phi$  existing on some interval containing  $t_0$ .

2b =  $\begin{pmatrix} \frac{\partial f_1}{\partial x_1} \\ \frac{\partial f_2}{\partial x_1} \\ \frac{\partial f_3}{\partial x_1} \end{pmatrix}$

19

So here if you look at  $f(t, x)$ ,  $x$  is continuous. If you look at here, this each component is continuous basically. So  $tx^2+x^3$  is continuous,  $\cos$  of  $tx^1+t^2x^3$  is continuous,  $x^1-x^2$  is continuous. So each component is continuous, so we can say that  $f$  is continuous for all  $t$  such that modulus of  $t$  is  $< \infty$  and for all  $x$  such that modulus of  $x$  is  $< \infty$ . Now look at the partial derivative of  $f$ .

So partial derivative of  $f$  with respect to  $x^1$  is  $0, \cos t$  and  $1$ , so that you can easily verify. You look at  $\frac{df}{dx^1}$  means here we can write  $\frac{df_1}{dx^1} \frac{df_2}{dx^1}$  and  $\frac{df_3}{dx^1}$ . So here the derivative means this, so  $\frac{df_1}{dx^1}$  is basically there is no component of  $x^1$ . So you can say  $\frac{df_1}{dx^1}$  is  $0$  and here it is  $\cos$  of  $t$  and here it is  $1$ . So we can write down  $\frac{df}{dx^1}$  as  $0 \cos t 1$ .

Similarly, we can find out  $\frac{df}{dx^2}$ , this is  $t, 0, -1$  and  $\frac{df}{dx^3}$  is  $1, t^2$  and  $0$ . So we can say that the partial derivative corresponding to  $x^1, x^2$  and  $x^3$  are also continuous for all  $t$  such that modulus of  $t$  is  $< \infty$  and for all  $x$  such that mod of  $x$  is  $< \infty$ . So it means that here that  $f$  is continuous and partial derivative is also continuous for all for the entire four-dimensional space that is  $t, x^1, x^2, x^3$  space and through any point  $t_0, \eta$ , there passes a unique solution  $\phi$  existing on some interval containing  $t_0$ .

So it means that here your solution will exist which passes through a given point  $t_0, \eta$  and containing the initial condition  $t_0$ . This is regarding this example number 3. So we have discussed the existence and uniqueness theorem for some system  $\dot{x} = f(t, x)$  and we have seen that solution exists provided your any interval  $I$  such that your  $f$  is continuous and partial derivative of  $f$  is continuous in that region.

And if that region happens to be the entire space, then solution will exist for all say  $t$  such that norm of that solution remains bounded and we have seen some two examples based on that. Now let us move to a particular form of  $f(t, x)$  such that  $f(t, x)$  is linear in terms of  $x$ . So now consider the concept like linear system.

**(Refer Slide Time: 33:17)**

## Linear System ✓

### Definition 4

In system (1), if the functions  $f_1, \dots, f_n$  are linear with respect to dependent variables  $x_1, \dots, x_n$ , then the system of equations is said to be a linear system.

The system which is not linear is called a nonlinear system. ✓

The most general system of  $n$  first order linear equations has the form

$$\begin{aligned}
 \checkmark \frac{dx_1}{dt} &= a_{11}(t)x_1 + \dots + a_{1n}(t)x_n + f_1(t) \\
 &\vdots \\
 \checkmark \frac{dx_n}{dt} &= a_{n1}(t)x_1 + \dots + a_{nn}(t)x_n + f_n(t). \checkmark
 \end{aligned}
 \tag{7}$$

$f(t, c_1x_1 + c_2x_2) = c_1f(t, x_1) + c_2f(t, x_2)$

$a = \frac{d}{dt}(t, x)$   
 $f = \frac{d}{dt}(t, x)$

So in system 1 that is  $\dot{x} = f(t, x)$ , if the function  $f_1$  to  $f_n$  where  $f$  is given as  $f_1$  to say  $f_n$ , if these function  $f_1$  to  $f_n$  are linear with respect to dependent variable  $x_1$  to  $x_n$ , then the system of equation is said to be a linear system. So it means that if we have system like this  $\dot{x} = f(t, x)$  and if  $f$  is linear corresponding to  $x$  then we say this system as a linear system. What do you mean by that  $f$  is linear in terms of  $x$ ?

So here you please recall the condition that  $f(t, c_1x_1 + c_2x_2)$ , if we can write this as  $c_1f(t, x_1) + c_2f(t, x_2)$  if it satisfy this condition, then we say that  $f$  is a linear function corresponding to the dependent variable  $x$ . So we say that if  $f$  satisfies the following condition, then we call the system of equations as a linear system of equation and the system which is not linear we call that system as a nonlinear system.

And we can check that the most general system of  $n$  first-order linear equation has the following form. That is  $\frac{dx_1}{dt} = a_{11}(t)x_1 + a_{12}(t)x_2 + \dots + a_{1n}(t)x_n + f_1(t)$  and similarly the  $n$ th equation  $\frac{dx_n}{dt} = a_{n1}(t)x_1 + a_{n2}(t)x_2 + \dots + a_{nn}(t)x_n + f_n(t)$ . So here we can write that this is the most general system of  $n$  first-order linear differential equation and is given by equation number 7 here.

**(Refer Slide Time: 35:09)**

## Homogeneous

### Definition 5

The system (7) is said to be a homogeneous system if each of the functions  $f_1, f_2, \dots, f_n$  is identically zero.

A System is said to be nonlinear if it is not a linear system .

Let  $A(t)$  be an  $n \times n$  matrix with elements  $a_{ij}(t)$ , and, let  $F(t)$  and  $x$  be vectors with components  $f_1, \dots, f_n$  and  $x_1, \dots, x_n$  respectively. Then, we can write (7) in the following simpler form

$$\frac{dx}{dt} = A(t)x + F(t), \quad (8)$$

Now if in the system 7 if all these right hand side  $f_1 t$  and  $f_n t$  are say 0 function, then we call the system 7 as homogenous system. So it means that the functions which are not involving any dependent variable and it is a function of independent variable  $t$  such that so if these functions are 0 for all  $t$ , then we call our linear system as a homogenous linear system and a system is said to be nonhomogeneous system if it is not a homogenous system.

So it means that if these functions  $f_1$  to  $f_n$ 's are not identically 0, it means that exists one function which are say nonzero for at least few values of  $t$ . Then, we call this system 7 as a nonhomogeneous system of differential equation. Now we can find out the compact notation of equation number 7 and for that notation let us assume that  $A_t$  be a  $n \times n$  matrix with the element  $a_{ij} t$  and let  $F_t$  and  $x$  be vectors with components  $f_1$  to  $f_n$  and  $x_1$  to  $x_n$ .

**(Refer Slide Time: 36:48)**

$$\text{where } A(t) = \begin{pmatrix} a_{11}(t) & a_{12}(t) & \cdots & a_{1n}(t) \\ a_{21}(t) & a_{22}(t) & \cdots & a_{2n}(t) \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1}(t) & a_{n2}(t) & \cdots & a_{nn}(t) \end{pmatrix}, x = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}, \text{ and } F(t) = \begin{pmatrix} f_1 \\ \vdots \\ f_n \end{pmatrix}.$$

Moreover, if  $x_1(t), \dots, x_n(t)$  satisfy the initial conditions

$$x_1(t_0) = x_1^0, \dots, x_n(t_0) = x_n^0$$

then  $x(t)$  satisfies the following initial-value problem

Then, we can write down the equation number 7 as follows  $\frac{dx}{dt} = A(t)x + F(t)$  of  $t$  where  $A(t)$  is given as  $a_{11}(t)$  to  $a_{12}(t)$  up to  $a_{n1}(t)$  and so on and  $x$  is a vector defined as  $x_1, x_2, \dots, x_n$  and  $F(t)$  is a vector having component  $f_1$  to  $f_n$ . Moreover, if  $x_1(t_0) = x_1^0$  and  $x_n(t_0) = x_n^0$ , then  $x(t)$  satisfy the following initial-value problem.

**(Refer Slide Time: 37:29)**

$$\frac{dx}{dt} = A(t)x + F(t), \quad x(t_0) = x^0,$$
 where  $x^0 = \begin{pmatrix} x_1^0 \\ \vdots \\ x_n^0 \end{pmatrix}$ , and  $F(t) = \begin{pmatrix} f_1 \\ \vdots \\ f_n \end{pmatrix}$ .

**Definition 6**  
 If  $A(t) \equiv A$ , where  $A$  is a constant matrix, then the system (8) is called a autonomous system of linear equations, otherwise, the system is called a non-autonomous system of linear equations.

$x' = Ax$

IT ROORKEE
NPTEL ONLINE CERTIFICATION COURSE
23

So along with the differential equation if  $x(t)$  satisfy the initial condition, then we can say that  $x(t)$  satisfy the following initial-value problem that is  $\frac{dx}{dt} = A(t)x + F(t)$  of  $t$  such that  $x(t_0) = x^0$  where  $x^0$  is defined as  $x_1^0$  to  $x_n^0$  and  $F(t)$  is given as the vector-valued function  $f_1$  to  $f_n$ . So it means that from now onwards, we use compact notation to discuss the linear system of differential equation.

Now if the coefficient matrix that is  $A(t)$ ,  $A$  is identically  $= A$ , it means that  $A(t)$ ,  $A$  is not a function of  $t$ , it means that its components are constant values. Then, we can say that if  $A$  is a constant matrix then the system 8 is called an autonomous system of linear equation. Otherwise, the system is called a non-autonomous system of linear equation. So it means that here if we look at the coefficients here if all the coefficients are independent of  $t$  it means just a constant value, some real constant.

**(Refer Slide Time: 38:41)**

$$\text{where } A(t) = \begin{pmatrix} a_{11}(t) & a_{12}(t) & \cdots & a_{1n}(t) \\ a_{21}(t) & a_{22}(t) & \cdots & a_{2n}(t) \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1}(t) & a_{n2}(t) & \cdots & a_{nn}(t) \end{pmatrix}, x = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}, \text{ and } F(t) = \begin{pmatrix} f_1 \\ \vdots \\ f_n \end{pmatrix}.$$

Moreover, if  $x_1(t), \dots, x_n(t)$  satisfy the initial conditions

$$x_1(t_0) = x_1^0, \dots, x_n(t_0) = x_n^0$$

then  $x(t)$  satisfies the following initial-value problem

$$x' = Ax + F$$

Then, your system  $x' = Ax + F$  is known as autonomous system, otherwise it is known as non-autonomous system. So this is an example of non-autonomous system and the system  $x' = Ax$  is said to be an autonomous system of linear equations. Now let us discuss one particular case of linear system that is linear homogenous system for which consider the linear system of differential equation  $dx/dt = Ax + Ft$  where  $x$  is given as  $x_1$  to  $x_n$ ,  $A$  is given as  $a_{ij}$  and  $F$  is given as  $f_1$  to  $f_n$ .

**(Refer Slide Time: 39:21)**

### Linear Homogeneous system

Consider the linear system of differential equations

$$\frac{dx}{dt} = A(t)x + F(t), \quad x = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix},$$

$$A(t) = \begin{pmatrix} a_{11}(t) & \cdots & a_{1n}(t) \\ \vdots & \ddots & \vdots \\ a_{n1}(t) & \cdots & a_{nn}(t) \end{pmatrix}, \text{ and } F(t) = \begin{pmatrix} f_1 \\ \vdots \\ f_n \end{pmatrix}. \quad (9)$$

Now if you look at this  $F$ , if this  $F$  is nonzero, then nonzero vector-valued function then we call it a nonhomogeneous system and if  $F$  is identically  $=0$  for all  $t$  then we call this as a linear homogenous system. So in this slide, we are assuming that  $F$  is identically  $=0$  function.

**(Refer Slide Time: 39:47)**

*x' = f(t, x)* ✓

✓ To initiate the study of linear homogeneous equation (there is no external force  $F(t)$  in equation (9)), we first make sure that the system has a solution.

So first we state the existence and uniqueness theorem without proof. The proof of the following theorem can be given in a similar manner as we did in the proof of Picard's Theorem.

The only noticeable change is the change of  $|\cdot|$  function with a suitable norm  $\|\cdot\|$  function. We may define a norm of a matrix  $A$ , denoted by  $\|A\|$ , in several ways and all the norms are equivalent to each other (recall that on a finite dimensional vector space any norm is equivalent to any other norm).

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 25

So it means that to initial the study of linear homogenous equation that is there is no external force  $F_t$  in equation 9.

### Linear Homogeneous system

Consider the linear system of differential equations

$$\frac{dx}{dt} = A(t)x + F(t), \quad x = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix},$$

$$A(t) = \begin{pmatrix} a_{11}(t) & \dots & a_{1n}(t) \\ \vdots & \ddots & \vdots \\ a_{m1}(t) & \dots & a_{nn}(t) \end{pmatrix}, \quad \text{and } F(t) = \begin{pmatrix} f_1 \\ \vdots \\ f_n \end{pmatrix}. \quad (9)$$

✓  $F(t) \equiv 0 \quad \forall t \in I$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 24

That is we are assuming that this  $F_t$  is identically=0 function for all  $t$  belongs to this interval  $I$ . So it means that to initiate the study of linear homogenous equation, we first make sure that the system has a solution. So first thing is that system has a solution and then we try to find out that what are the type of solution and how we can find out the properties of solutions of the homogenous equation.

So first we state the existence and uniqueness theorem without any proof and the proof of the theorem can be given in a similar manner as we did in the proof of the Picard's theorem. If you remember the scalar-valued function  $x' = f(t, x)$  and under some condition on  $f$  that is

if  $f$  satisfy the ellipses condition or we can say that partial derivative  $f$  are say continuous. Then, we can find out that in this system this equation has a solution and that solution is unique in some neighborhood of initial point that is  $t_0$ .

So the only change in the case of vector-valued system of linear equation and scalar-valued system of linear equation is the say notation of modulus function. So in the scalar-valued function, this modulus represent the absolute difference or absolute difference between the points but now here this norm this modulus is represented by norm of the corresponding norm.

So here we can restate this theorem, existence and uniqueness theorem, the only change we are going to consider is the change in terms of distance function that is modulus function. So here in case of modulus, we are going to use the norm function. So the only noticeable change is the change of modulus function with the suitable norm function and we may define a norm of a matrix  $A$  denoted by norm of  $A$  and it can be defined in several ways and all the norms are equivalent to each other.

And there is a property of a finite dimensional vector space that whatever norm you are going to define, they are going to be equivalent norm, equivalent means it is not the same norm but the qualitative properties is same whatever norm you will choose okay. So this we are going to discuss in next lecture. So for this lecture we will stop and will discuss in next, will continue our study in next lecture. Thank you very much for listening us. Thank you.
