Lecture: 31
Application of Invariant Subspaces - 1

(Refer Slide Time: 00:58)

Lemma: Let T be a LO on a f.d.v.s V over F , such that the minimal polynomial of T is product of linear factors i.e.

$$p = (x-c_1)^{r_1} (x-c_2)^{r_2} \dots (x-c_k)^{r_k}$$

where c_1, c_2, \dots, c_k are distinct constants from F .
 Let W be a proper subspace of V , which is invariant under T , then $\exists \alpha \in V$ such that

(i) $\alpha \notin W$
 (ii) $(T-cI)\alpha \in W$, where c is an eigen value of T .

Welcome to lecture series on advanced linear algebra. In our last lecture, we have proved one result if T be a linear operator on a finite dimensional vector space V over the field F such that the minimal polynomial of the T is a product of linear factors that is if p is the minimal polynomial, $p = (x - c_1)^{r_1} (x - c_2)^{r_2} \dots (x - c_k)^{r_k}$ where $\{c_1, c_2, \dots, c_k\}$ are distinct eigenvalues or you can say distinct constant from F .

And if W be a proper subspace of V which is invariant under T , then $\exists \alpha \in V$, certainly nonzero α because I have taken W is a proper subspace, so there is this a nonzero α in V such that the T -conductor of α is a linear polynomial of the form of $(x-c)$. I mean to say (i) $\alpha \notin W$ (ii) $(T-cI)\alpha \in W$, where c is basically some eigenvalue of the operator T .

We shall utilize this result to prove the existence of simplified form of a linear operator defined over a finite dimensional vector space. I will talk about the triangular ability of the operator T .

(Refer Slide Time: 02:41)

Theorem: Let T be a linear operator on a f.d.v.s V over F .
 T is triangulable iff the minimal polynomial, p , is
 product of linear factors i.e.

$$p = (x - c_1)^{r_1} (x - c_2)^{r_2} \dots (x - c_k)^{r_k}$$

where, c_1, c_2, \dots, c_k are distinct constants from the field F .

Pf: \Rightarrow : Given the minimal polynomial of T , is product of
 linear factors i.e.

$$p = (x - c_1)^{r_1} (x - c_2)^{r_2} \dots (x - c_k)^{r_k}$$

We have to construct an ordered basis $B = \{\alpha_1, \alpha_2, \dots, \alpha_n\}$
 if \dim of V is n , such that

$$[T]_B = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1n} \\ 0 & a_{22} & a_{23} & \dots & a_{2n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & a_{nn} \end{bmatrix}$$

So this is a nice result I can write in terms of theorems like this. Let T be a linear operator on a finite dimensional vector space V over F , then T is triangulable if and only if the minimal polynomial say p is product of linear factors that is $p = (x - c_1)^{r_1} (x - c_2)^{r_2} \dots (x - c_k)^{r_k}$. Certainly $\{c_1, c_2, \dots, c_k\}$ will be eigenvalue or characteristic value of the operator and r_i , $i = 1$ to k is the positive integers and $\{c_1, c_2, \dots, c_k\}$ are distinct eigenvalues.

If it is the characteristic polynomial, then I could say $\{r_1, r_2, \dots, r_k\}$ are the algebraic multiplicity of the eigenvalues $\{c_1, c_2, \dots, c_k\}$, where $\{c_1, c_2, \dots, c_k\}$ are distinct constants from F . How to prove this result? To prove this result we shall use our previous results that if T be a linear operator on a finite dimensional vector space and the minimal polynomial is product of linear factors.

And if you consider W the proper subspace of V , then $\exists \alpha \in V$ such that $(T - cI)\alpha \in W$. So, I shall use this result or this lemma repeatedly to get the corresponding ordered basis under which the operator will be triangulable. So let me consider if part, given the minimal polynomial of T is product of linear factors, it is given to us. That is $p = (x - c_1)^{r_1} (x - c_2)^{r_2} \dots (x - c_k)^{r_k}$ this is given to us.

We have to construct an ordered basis B consisting of $\{\alpha_1, \alpha_2, \dots, \alpha_n\}$ if dimension of V is n

such that $[T]_B = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{1n} \\ 0 & a_{22} & a_{23} & a_{2n} \\ 0 & 0 & a_{33} & a_{3n} \\ 0 & 0 & 0 & a_{nn} \end{bmatrix}$. So, I will have a triangular matrix like this. We have

to construct an ordered basis B consisting $\alpha_1, \alpha_2, \dots, \alpha_n$ provided the dimension of the space is n such that the matrix representation will be triangular matrix.

(Refer Slide Time: 08:24)

\Rightarrow We want to show
 $T\alpha_j = a_{j1}\alpha_1 + a_{j2}\alpha_2 + \dots + a_{jj}\alpha_j$
 This will be done by repeated application of above lemma.
 Let $W = \{0\}$ i.e. zero subspace
 So, one finds a vector say $\alpha_1 \in V$ & $\alpha_1 \neq 0$.
 Using above lemma, one has
 $(T - cI)\alpha_1 = 0, \Rightarrow T\alpha_1 = c\alpha_1$
 Let $c = a_{11}$
 Now, consider $W_1 = \text{linear span of } \{\alpha_1\}$ —
 Whether W_1 is invariant under T or not. $\because W_1$ is eigen space
 associated to eigen value a_{11} , so W_1 is invariant under T .
 $\because W_1 \subset V$ $\because \dim$ of $V = n > 1$
 $\Rightarrow \exists 0 \neq \alpha_2 \in V$ such that $\alpha_2 \notin W_1$

This implies we want to show that $T(\alpha_j) = a_{j1}\alpha_1 + a_{j2}\alpha_2 + \dots + a_{jj}\alpha_j$. So we want to show

that there exist an ordered basis $\{\alpha_1, \alpha_2, \dots, \alpha_n\}$ such that $[T]_B = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{1n} \\ 0 & a_{22} & a_{23} & a_{2n} \\ 0 & 0 & a_{33} & a_{3n} \\ 0 & 0 & 0 & a_{nn} \end{bmatrix}$ will be

the characteristic values of the operator. So this will be constructed by repeated application of the previous results. This will be done by repeated application of above lemma.

So let $W = \{0\}$. So one can find $\alpha_1 \in V$ & $\alpha_1 \neq 0$, using above lemma, we have $(T - cI)\alpha_1 = 0$.
 So let $c = a_{11}$. This implies $T\alpha_1 = a_{11}c$, let $c = a_{11}$, just renaming the constant. Now consider W_1 as linear span of α_1 .

W_1 is basically another subspace of vector space V which is like this, $W_1 = \text{linear span of } \{\alpha_1\}$.
 Now question is whether W_1 is invariant under T ? See the way W_1 has been constructed it is basically eigenspace associated to eigenvalue $c = a_{11}$. Since W_1 is eigenspace associated to eigenvalue a_{11} , so W_1 is invariant under T . Now W_1 if the dimension of the vector space $n = 1$ then we are through it here.

Now $W_1 \subset V$ if dimension of $V = n > 1$. So, this implies $\exists 0 \neq \alpha_2 \in V$ such that $\alpha_2 \notin W_1$.

(Refer Slide Time: 13:41)

linearly independent? Already I have given the proof the way we have constructed the vector $\{\alpha_1, \alpha_2, \dots, \alpha_n\}$. I have utilized the concept that $\{\alpha_1, \alpha_2, \dots, \alpha_n\}$ are linearly independent. So, we will get n linearly independent vectors $\{\alpha_1, \alpha_2, \dots, \alpha_n\}$ which are linearly independent and

$T(\alpha_j) = \sum_{i=1}^n a_{ij} \alpha_i$. So, I will have a column matrix like this, $[T(\alpha_j)]_B = \begin{bmatrix} a_{1j} \\ a_{2j} \\ a_{3j} \\ \vdots \\ 0 \end{bmatrix}$. So, this implies

$$[T]_B = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{1n} \\ 0 & a_{22} & a_{23} & a_{2n} \\ 0 & 0 & a_{33} & a_{3n} \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & a_{nn} \end{bmatrix}.$$

(Refer Slide Time: 21:47)

⇐ Given that there exist an ordered basis $B = \{\alpha_1, \alpha_2, \dots, \alpha_n\}$ for V , such that

$$[T]_B = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ 0 & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & a_{nn} \end{bmatrix} = A$$

we have to show that the minimal polynomial is product of linear factors.

Certainly, characteristic polynomial of a triangular matrix A

$$f = (x - a_{11})(x - a_{22}) \dots (x - a_{nn})$$

So, it may be possible that T has k distinct eigen values c_1, c_2, \dots, c_k , with algebraic multiplicity e_1, e_2, \dots, e_k .

Now it is other way, only if. Given that there exist an ordered basis $B = \{\alpha_1, \alpha_2, \dots, \alpha_n\}$ for vector

space V such that $[T]_B = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{1n} \\ 0 & a_{22} & a_{23} & a_{2n} \\ 0 & 0 & a_{33} & a_{3n} \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & a_{nn} \end{bmatrix} = A$. We have to show that the minimal

polynomial is product of linear factors. Certainly, characteristic polynomial of triangular matrix this is equal to say A , is $f = (x - a_{11})(x - a_{22}) \dots (x - a_{nn})$. It may be possible that these characteristic values are repeated. So, it may be possible that T has k distinct eigenvalues $\{c_1, c_2, \dots, c_n\}$ with algebraic multiplicity say $\{e_1, e_2, \dots, e_n\}$.

(Refer Slide Time: 25:04)

$$f = (x - a_1)(x - a_2) \dots (x - a_n) = (x - c_1)^{e_1} (x - c_2)^{e_2} \dots (x - c_k)^{e_k}, \quad \sum_{i=1}^k e_i = n$$

Let ϕ be the minimal polynomial of T , then we know $\phi \mid f$

$$\Rightarrow \phi = (x - c_1)^{r_1} (x - c_2)^{r_2} \dots (x - c_k)^{r_k}, \quad \sum_{i=1}^k r_i \leq n$$

Ex. Let $A = \begin{bmatrix} 0 & 1 & 0 \\ 2 & -2 & 2 \\ 2 & -3 & 2 \end{bmatrix}$, be the matrix representation of
 L.O. T on \mathbb{R}^3 .

$$\det(xI - A) = (-1)^3 \begin{vmatrix} -x & 1 & 0 \\ 2 & -2-x & 2 \\ 2 & -3 & 2-x \end{vmatrix} = x^3$$

So then $f = (x - a_{11})(x - a_{22}) \dots (x - a_{nn}) = (x - c_1)^{e_1} (x - c_2)^{e_2} \dots (x - c_k)^{e_k}$, $\sum_{i=1}^k e_i = n$.
 So the characteristic polynomial is like this thing and this $\{c_1, c_2, \dots, c_n\}$ are coming from a_{ii} ,
 $i = 1$ to n . Let p be the minimal polynomial of T , then we know $\frac{p}{f}$, so this implies $p =$
 $(x - c_1)^{r_1} (x - c_2)^{r_2} \dots (x - c_k)^{r_k}$, $\sum_{i=1}^k r_i \leq n$.

So we see that if T is a linear operator defined over a finite dimensional vector space over the field F and if its minimal polynomial is product of linear factors, I mean to say the minimal polynomial is factorizable over the corresponding field, then the linear operator is triangulable that is there exist an ordered basis under which T can be represented by a triangular matrix.

So for examples let $A = \begin{bmatrix} 0 & 1 & 0 \\ 2 & -2 & 2 \\ 2 & -3 & 2 \end{bmatrix}$ be matrix representation of a linear operator T on \mathbb{R}^3 . One

can easily calculate, $\det(xI - A) = (-1)^3 \begin{bmatrix} x & 1 & 0 \\ 2 & 2-x & 2 \\ 2 & -3 & 2-x \end{bmatrix} = x^3$.

(Refer Slide Time: 28:59)

\Rightarrow Char. pol of A is x^3
 \therefore char. values are $0, 0, 0$
 We want find out an ordered basis say $B = \{\alpha_1, \alpha_2, \alpha_3\}$
 Such that
 $[T]_B = \begin{bmatrix} \lambda & & \\ & \lambda & \\ & & \lambda \end{bmatrix}$ i.e. triangular matrix
 Eigen vects associated $\lambda = 0$ $(A - \lambda I)X = 0$

$$\begin{bmatrix} 0 & 1 & 0 \\ 2 & -2 & 2 \\ 2 & -3 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

 $\Rightarrow \begin{cases} x_2 = 0 \\ x_1 + x_3 = x_2 \\ 2(x_1 + x_3) = 3x_2 \end{cases} \Rightarrow x_1 = -x_3$
 $\therefore \alpha_1 = (1, 0, -1)^T$, Let $W_1 = \text{LS}\{\alpha_1\}$

So this implies characteristic polynomial of A is x^3 . So characteristic values are $0, 0, 0$. Now we want to find out an ordered basis consisting $\{\alpha_1, \alpha_2, \alpha_3\}$ such that the matrix representation of T is a triangular matrix. We want to find out an ordered basis say $B = \{\alpha_1, \alpha_2, \alpha_3\}$ such that

$$[T]_B = \begin{bmatrix} 0 & a_{12} & a_{13} & a_{1n} \\ 0 & 0 & a_{23} & a_{2n} \\ 0 & 0 & 0 & a_{3n} \\ 0 & 0 & 0 & 0 \end{bmatrix}, \text{ i.e. triangular matrix. How to find it? So first I have to find out}$$

the eigenvector associated to eigenvalue equal to 0 that will give me the α_1 . So eigenvector associated to 0 eigenvalue. So this means that I will have, $(A - \lambda I)X = 0$ this mean

$$\begin{bmatrix} 0 & 1 & 0 \\ 2 & -2 & 2 \\ 2 & -3 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}.$$

So this implies, I will have the system $x_2 = 0$, $x_1 + x_3 = x_2$, $2(x_1 + x_3) = 3x_2$, this implies $x_2 = -x_3$. So α_1 I can construct is like this, $x_1 = 1$, so $x_2 = 0$, $x_3 = -1$, $\alpha_1 = (1, 0, -1)^T$. So I am working for the matrix A , so this is basically associated to the matrix A only, Now second one I have to obtain let $W_1 = \text{LS}\{\alpha_1\}$ that is a scalar multiple of $(1, 0, -1)^T$.

So if it is, then I will have many solutions no doubt, but I can take scalar quantity $c = 1$. I can have like this.

(Refer Slide Time: 33:18)

$$AX = \alpha_1, \quad x_2 = 1$$

$$2(x_1 + x_3) - 2x_2 = 0, \quad x_1 + x_3 = x_2 = 1, \quad x_3 = 0, \quad x_1 = 1$$

$$2(x_1 + x_3) - 3x_2 = -1$$

$$2(x_1 + x_3) = 2$$

$$\alpha_2 = (1, 1, 0)^T \quad (A - 0I)\alpha_2 = \alpha_1$$

$$AX = \alpha_1 + \alpha_2 = (1, 0, -1)^T + (1, 1, 0)^T$$

$$= (2, 1, -1)^T$$

$$AX = \begin{pmatrix} 2 \\ 1 \\ -1 \end{pmatrix} \quad x_2 = 2$$

$$2(x_1 + x_3) - 2x_2 = 1, \quad 2(x_1 + x_3) = 5$$

$$2(x_1 + x_3) - 3x_2 = -1$$

Putting $x_1 = 0, x_3 = 5/2$

$$\alpha_3 = (0, 2, 5/2)^T, \quad B = [\alpha_1, \alpha_2, \alpha_3], \quad (T)_B = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Again system, I will have basically $AX = \alpha_1, x_2 = 1, 2(x_1 + x_3) - 2x_2 = 0$ this implies $x_1 + x_3 = x_2 = 1, x_3 = 0, x_1 = 1, 2(x_1 + x_3) - 3x_2 = -1$, So this implies that I will have $x_2 = 1$ and this is giving me $2(x_1 + x_3) = 2$. So I will have $x_3 = 0$ and $x_1 = 1$. So this means α_2 , I can construct as $1, \alpha_2 = (1, 1, 0)^T$. So the construction that α_2 such that here I have see $(A - 0I)\alpha_2 = \alpha_1$.

Now α_2 is known, α_3 is also known. Now let me consider again $AX = \alpha_1 + \alpha_2 = (1, 0, -1)^T + (1, 1, 0)^T = (2, 1, -1)^T$. So $AX = \begin{bmatrix} 2 \\ 1 \\ -1 \end{bmatrix}$.

Now I have to solve this system. If I solve this system, I will have what $x_2 = 2, 2(x_1 + x_3) - 2x_2 = 1$ and $2(x_1 + x_3) - 3x_2 = -1$. Now I have to solve this system. So if I substitute $x_2 = 2$, this implies that $2(x_1 + x_3) = 5$, Third one also gives me, so put $x_2 = 2$, so again same equation. So what I will do? I will take putting $x_1 = 0$, I have $x_3 = \frac{5}{2}$.

So I will have $\alpha_3 = (0, 2, \frac{5}{2})^T$. You can check $A\alpha_3 = \begin{bmatrix} 2 \\ 1 \\ -1 \end{bmatrix}$ linear combination of α_1 and α_2 .

Now $B = (\alpha_1, \alpha_2, \dots, \alpha_n)$, $[T]_B = \begin{bmatrix} 0 & a_{12} & a_{13} & a_{1n} \\ 0 & 0 & a_{23} & a_{2n} \\ 0 & 0 & 0 & a_{3n} \\ 0 & 0 & 0 & 0 \end{bmatrix}$. So what is the triangular matrix? So

diagonal entry will be 0 because eigenvalue is 0 and this one will be what? We have to see what is the coefficient of $T(\alpha_1)$ and $T(\alpha_2)$ and $T(\alpha_3)$, so that it will give me a triangular matrix.

So you have seen that one can find an ordered basis under which the operator can be represented by a triangular matrix. But this representation is not unique because it depends on the constant scalar quantity. You take different scalar having coefficient 1 and 1, if you take different coefficient I will have different solution, but it is possible to have an ordered basis under which one can have the triangular representation of the operator. So, we will continue the applications of invariance of space in our next class also. Thank you.
