Stability Equilibrium Points Continued

Welcome back. So, in the previous class we were discussing about Stability of an Equilibrium Point of our autonomous system. And if you look at the definition, so there is a need to isolate our equilibrium point. So, let me start with that thing.

(Refer Slide Time: 00:51)

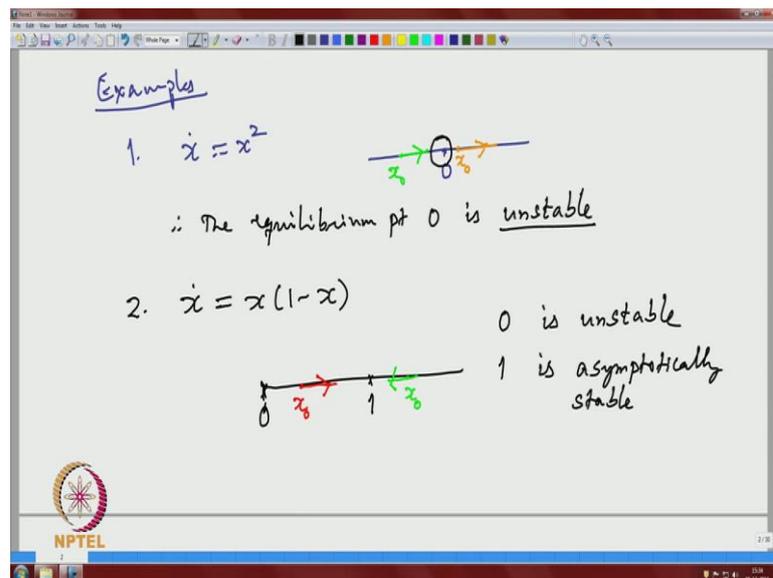

So, consider, so this I always refer to system 1. So, let \bar{x} be a equilibrium point of 1. So, again let me remind you that is, it is the right hand side is 0. So, if there are n equations here, so it is \bar{x} is common 0 of all those functions.

So, \bar{x} is said to be isolated equilibrium point. So, in most of the examples we consider they are all isolated. There will be some examples where the equilibrium points will not be isolated. We will indicate those things. If there exists r positive such that, so I introduce a notation here. So, $B_r(\bar{x})$, so this is what we call open ball centered at \bar{x} with radius r . So, this is set of all x in \mathbb{R}^n such that whose distance from \bar{x} is less than r . So, this is the open ball does not contain any other equilibrium point of 1.

So, geometrically I just want to draw that ball. So, this is \bar{x} . So, this is, so in 2 dimensions you can imagine this is really a ball. So, this is and this interior should not contain any other equilibrium point of 1. The reason for this thing; since, we are in the definition of stability you recall. We want to start a solution very close to \bar{x} and we want to remain there. So, if there are other equilibrium points then that solution may go to tend to that other equilibrium points.

So, you are just wants to avoid, so we just isolate it. So, that is why this isolation. So, so once this, we take \bar{x} to an isolated point. So, you reframe the definition of stability and asymptotic stability of an isolated point. So, I will not repeat these things. So, here after unless, here after we consider only isolated equilibrium points of course unless explicitly stated. So, this is usual before we move on further. So, immediately let us consider again those examples we did in the last class.

(Refer Slide Time: 05:27)

So, examples, so again start with 1 d \dot{x} equal to x square and 0 is the only equilibrium point here. So, this is 0 and certainly it is isolated, because there are no other equilibrium points, so much more than isolated. And we saw, so if we start a solution with initial value on the when x_0 is positive. So, it will move in that direction and if we start a solution in x_0 negative, then it will move. So, this we have already worked out.

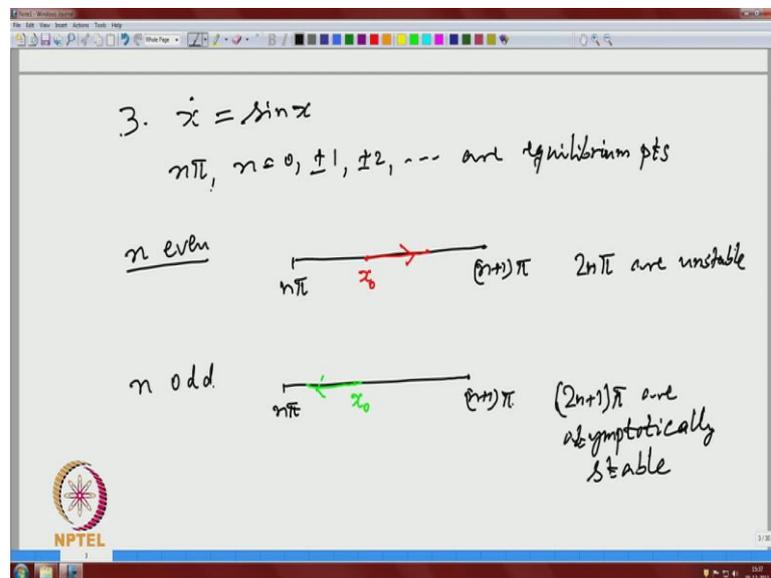

So, if I start the solution in a neighborhood of 0 and left side, it approaches zero. But right side it goes away from 0. So, therefore the equilibrium point, the only equilibrium

point 0 is unstable. Just look at the definition again. So, for stability we want the solution to remain all the time in that neighborhood. But here on the right side of the origin in this case, the solution moves away from the 0. So, that is why it is unstable.

The second example logistic model. So, normalized several things. So, just we, so here the equilibrium points are 0 and 1. So, obviously they are isolated. So, I do not have to stress that thing 0 and 1. And again we have done the analysis. So, if we start a solution between 0 and 1. The solution the orbit moves towards right and it in fact approaches 1. And if we start the orbit through x_0 which is bigger than 1, then it moves towards 1 again.

So, looking at this picture and just again look at the definition of the stability instability. So, 0 let go back to blank. So, 0 is unstable and 1 is asymptotically stable. So, we can see when there are more equilibrium points. So, the nature of one equilibrium point may be different from the other one within the same system. So, for example, see this. So, one is unstable and another equilibrium point is asymptotically stable.

(Refer Slide Time: 09:30)

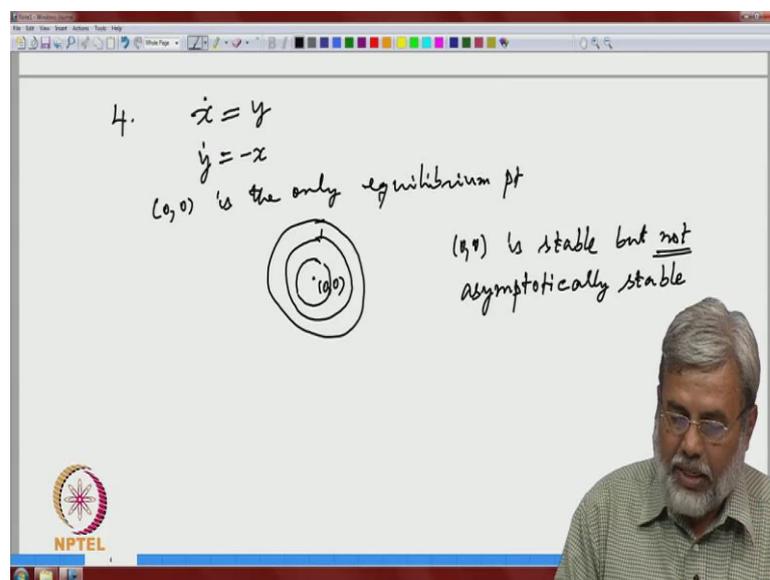

So, now let us move to that the one dimensional cosine of the pendulum equation. So, here \dot{x} equal to $\sin x$. So, we did this in great detail in the morning. So, in fact one can get explicit solutions. So, that was an exercise. So, here $n\pi$ n equal to 0 plus or minus 1 are equilibrium points. And do you saw, the nature of orbits changes with n

being odd or even. So, let me just consider the case of let me write separately. So, n even that is the case.

So, let me just draw here $n\pi$ $n + 1\pi$. So, if I start orbit through a point here, in this interval open interval then the orbit moves towards that. And n odd same thing $n\pi$ $n + 1\pi$. And now, I start the orbit from $x = 0$ here and it moves towards that. So, you see that this when n is even, so this $2n\pi$ are unstable and $2n + 1\pi$. So, these are all odd multiples of π are asymptotically stable.

(Refer Slide Time: 12:08)

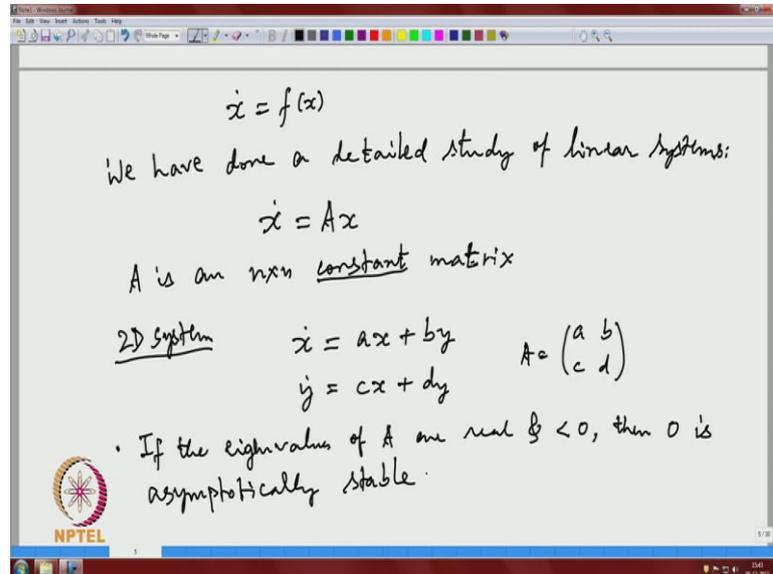

So, finally one more example. So, pendulum with small oscillations. So, this is the approximation, so 2 D. So, this is 2 D example. So, we saw in the previous lecture the orbits are nothing but circles. So, here again $(0,0)$ is the only equilibrium point. So, it is isolated naturally. And all our orbits, so this is $(0,0)$ are circles. So, if I start an orbit, so there are all concentric circles. So, though it has come here, so it is concentric. So, no doubt if you start in a small neighborhood around origin, the orbit the positive orbit stays close to an origin there.

But in any case it will never it can never converge to the origin as t goes to infinity, because it is always lies on their circle. So, here we have an example this $(0,0)$ 2 D case is stable, but not asymptotically stable. So, this is a very typical example and we coat it at many places not asymptotical. So, stability does not automatically imply asymptotic

stability, but asymptotic stability requires stability. So, asymptotic stability is something more than stability.

(Refer Slide Time: 14:26)

So, now we have defined stability and asymptotic stability of an isolated equilibrium point. But then how do I decide. So far, so I have worked out few examples that is fine. But suppose I want to decide, when a given equilibrium point will be stable or unstable or asymptotic stable. What should I do? So, that is next question and we have already done enough of this in a special case.

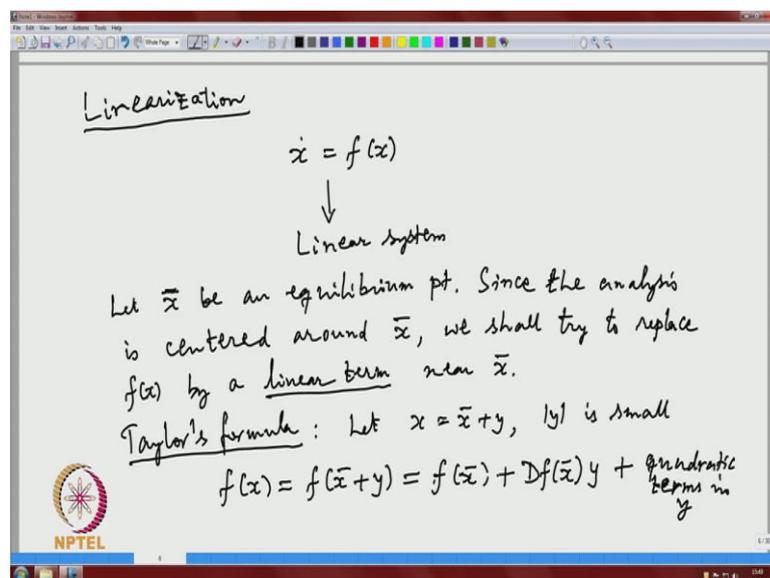

So, that is our starting point. So, we have done a detailed study of linear systems that is our guide impression. So, let me just write that. So, that $f(x)$ a special thing here, so a x . So, A is an n by n constant matrix. So, its entries do not depend on t . So, because we want an autonomous system constant matrix. Let me just recall what we have done there. So, let me just instead of writing a general system let me just write a 2D system.

And recall some of the facts we did. So, in this case we have only two unknowns. So, $\dot{x} = ax + by$ and $\dot{y} = cx + dy$ and this A will be in this case just this 2 by 2 matrix. And we have also learnt that how the nature of Eigen values of this 2 by 2 matrix has played an important role in the description of the trajectories orbits of this system. So, let me just recall that.

So, if so let me just recall this, if the Eigen values of a are real and negative less than 0 then. So, you recall for this linear system 0 is a equilibrium point when the determinant is not 0, 0 is the only equilibrium point. So, in case we are assuming Eigen values are both negative. So, there are non zero. So, a is a nonsingular matrix 0 ((Refer Slide Time: 18:06)) equilibrium point and 0 is asymptotically stable.

And again, several cases let me not spend time on that. So, if the Eigen values are real opposite sign, then the origin will be unstable. And so many, so many conditions. So, that is we have already learnt that. So, that is that is a special system the linear system. And now, the question is can we exploit all that knowledge to study the non-linear systems. So, that is the next question.

(Refer Slide Time: 19:11)

So, can we exploit whatever we learnt from the linear system and apply it to non-linear system and this is called linearization process. So, this is the first step in understanding the stability of equilibrium points of a non-linear system linearization. So, what does that mean? So, we are given this system general system our f of x. And do you want to convert this to a linear system, but where? So, again remember our interest is, so let x bar be an equilibrium, so isolated equilibrium.

And our interest is to examine whether x bar is stable or not. So, we are in a very small neighborhood around x bar. So, everything is taking place there. So, we are interested in solutions which start very close to x bar to stay there or whether they are leaving or not.

So, everything the analysis is centered around \bar{x} . So, since the analysis is centered around \bar{x} , we shall try to replace $f(x)$ by a linear term.

So, this is linear term near \bar{x} and again this is not new for us in calculus all the time we do it. So, given a complicated function, suppose we are interested in the nature of that function near some point. So, we have Taylor's expansion around that point. And so we can approximate that given function by a linear function or a quadratic function etcetera. So, we already have that in calculus we do that. And similarly here, so this is multivariable calculus.

So in fact, it is also called Taylor formula and it can be derived from one variable calculus and this will be included in the preliminaries. So, let me explain that Taylor's formula. So, let x equal to $\bar{x} + y$. So, y is small because, we are just concentrating near \bar{x} . So, I would like to write that. So, $f(x)$ now will be $f(\bar{x} + y)$. So, if it were just 1 variable and just 1 function, what generally we do here is \bar{x} plus derivative of f at \bar{x} into y plus second derivative of \bar{x} at f at \bar{x} y^2 etcetera.

So, here since we are in n dimension, n generally bigger than 1. So, that thing is replaced by what I call it $Df(\bar{x})y$ plus quadratic terms in y . So, let me explain that. So, remember this f means there are f_1, f_2, \dots, f_n . So, for each f_i you can do it and then this is will be. So, this is a vector this is a vector, so this is a vector. So, y is already a vector. So, this is a matrix.

(Refer Slide Time: 24:27)

Handwritten notes on a whiteboard:

Taylor's formula: Let $x = \bar{x} + y$,

$$f(x) = f(\bar{x} + y) = \underbrace{f(\bar{x})}_{=0} + Df(\bar{x})y + \underbrace{\text{quadratic terms in } y}_{O(|y|^2)}$$

$Df(\bar{x}) = \text{Jacobian of } f \text{ at } \bar{x} = n \times n \text{ matrix}$

$$= \left(\left(\frac{\partial f_i}{\partial x_j} \right) \right)_{1 \leq i, j \leq n}$$
$$f(x) = f(\bar{x} + y) = Df(\bar{x})y + O(|y|^2)$$

Recall $\dot{x} = f(x) \Rightarrow \frac{d}{dt}(\bar{x} + y) = f(\bar{x} + y) = Df(\bar{x})y + O(|y|^2)$

NPTEL logo is visible in the bottom left corner of the whiteboard.

So, $Df(\bar{x})$ is called Jacobian of f at \bar{x} and this is a n by n matrix. So, if it is n by n matrix. So, I should tell you the entries of that thing. So, this is my matrix notation. So, I put two brackets. So, $\left(\left(\frac{\partial f_i}{\partial x_j} \right) \right)$ element is this. So, this is the matrix that is the matrix. And this one, this quadratic terms in y we write it has $O(|y|^2)$ just for.

So, let me again repeat that thing, let me rewrite it. So now, we have, so $f(x)$ is equal to $f(\bar{x} + y)$. Let me repeat it again not do that thing. So, \bar{x} is an equilibrium point. So, this will be 0 plus O . So, remember now. So now, I write that. So, recall \dot{x} now is equal to $f(x)$. So, this implies $\dot{\bar{x}} = f(\bar{x}) = 0$. So, let me write $\frac{d}{dt}(\bar{x} + y) = f(\bar{x} + y) = Df(\bar{x})y + O(|y|^2)$ and now y , that is fine.

(Refer Slide Time: 27:31)

$Df(\bar{x}) = \text{Jacobian of } f \text{ at } \bar{x} = n \times n \text{ matrix}$
 $= \left(\left(\frac{\partial f_i}{\partial x_j} \right) \right)_{1 \leq i, j \leq n}$

$f(x) = f(\bar{x} + y) = Df(\bar{x})y + O(|y|^2)$

Recall $\dot{x} = f(x) \Rightarrow \frac{d}{dt}(\bar{x} + y) = f(\bar{x} + y) = Df(\bar{x})y + O(|y|^2)$

Consider $\dot{y} = Df(\bar{x})y \quad (2)$

This is called the linearized eqn of (1) at \bar{x}

So now, we define the linear approximation. So, consider. So now, you see. So, this one this is a constant. So, this is just y dot and in the first approximation in the linear approximation I ignore this quadratic terms. So, this y dot is equal to $Df(\bar{x})y$ this is called. So, let me call it to, this is called the linearized equation of 1 at x bar. So, that is important. So, we are just concentrating on that equilibrium point.

So, if there are more equilibrium points, then we get more linearized equations. So, each one could be different because, this matrix changes remember that this matrix. So, that changes. And one important thing I want to like to stress that. So, we started with very minimal hypothesis on the right hand side f in order to have this one.

(Refer Slide Time: 29:14)

$f(x) = f(\bar{x}+y) = Df(\bar{x})y + O(|y|^2)$

Recall $z = f(x) \Rightarrow \frac{d}{dx}(\bar{x}+y) = f(\bar{x}+y) = Df(\bar{x})y + O(|y|^2)$

Consider $y = Df(\bar{x})y \quad (2)$

This is called the linearized eqn of (1) at \bar{x}

Here we require f is C^2 , i.e. f_1, \dots, f_n all possess cont. 2nd order partial derivatives

So, here we require. So, this I was telling in the beginning as we go along, we put more hypothesis on f . So, f is a C^2 function C^2 vector otherwise f is C^2 . So, that is f_1, f_2, \dots, f_n all possess continuous second order partial derivatives. The second order, first order already you have seen it here that is comes in the Jacobian. The second order derivatives are required in order to write this one. So, that is why we require that C^2 .

But most of our examples they are all polynomials. Polynomials are in fact not only C^2 , they are infinitely a many times differentiable, so no problem. So now, few more definitions we will go to examples.

(Refer Slide Time: 30:42)

Consider $\dot{y} = Df(\bar{x})y$ (2)

This is called the linearized eqn of (1) at \bar{x}

Here we require f is C^2 , i.e. f_1, \dots, f_n all possess cont. 2nd order partial derivatives

If 0 is stable (asymptotically stable, unstable) for (2), we say that \bar{x} is linearly stable (-----) for (1)

So, now this is just a linear system. So, we have to just concentrate on the Eigen values of this thing. So, let me just. So, if 0 is stable asymptotically stable this is definition stable, unstable for 2. Now, you consider the linear system 2 and decide. So, 0 is an equilibrium point for system 2. So, if 0 is stable or asymptotically stable or unstable for 2. We say that \bar{x} is linearly stable asymptotically stable etcetera for 1.

(Refer Slide Time: 32:36)

all possess cont. 2nd order partial derivatives

If 0 is stable (asymptotically stable, unstable) for (2), we say that \bar{x} is linearly stable (-----) for (1)

This analysis is called Linear Stability Analysis

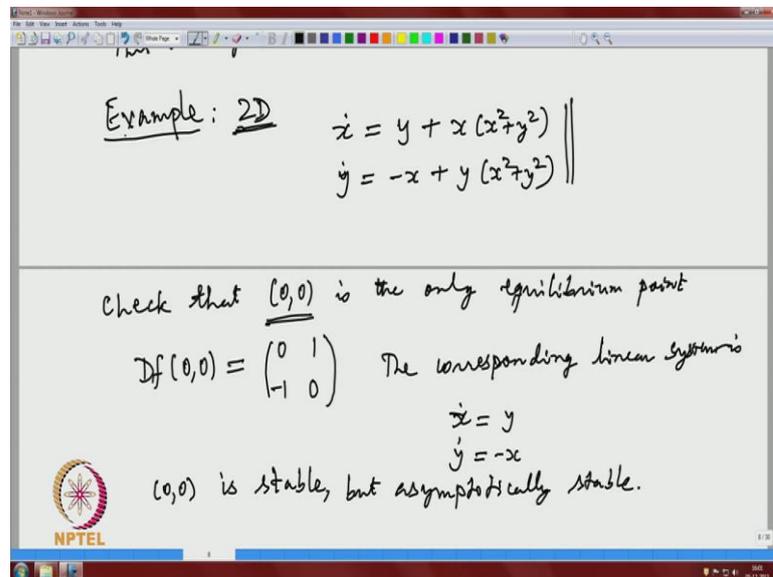

Example: 2D $\dot{x} = y + x(x^2 + y^2)$
 $\dot{y} = -x + y(x^2 + y^2)$

And this analysis is called linear stability analysis. So, it is not only done in case of n d's it is done in p d's and even more general equations in infinite dimensional spaces linear

stability analysis. And this is routinely done by physicists and engineers. But one should not stop there. Linear stability analysis gives you something, but it may not with you see through some examples, it may not be the case with original non-linear system. So, you just consider one example.

So, example before we go on further, so 2 D. So now, hereafter the most examples will be 2 D. So, this is again a very standard one to indicate that linear stability analysis will not indicate anything regarding the original system plus $x^2 + y^2$. there are some good cases, we will as we go along we will mention those things. So, this is a very standard 2 D example.

(Refer Slide Time: 34:49)

So, check that. So, sometimes it is easy sometimes you have to really do some algebra. So, this is an exercises for you, check that 0 0 is the only equilibrium point. So, let us try to do the linear analysis. So, this is my. So, I have to just evaluate the Jacobian matrix at the origin, because this is the only. So, you can easily check that, so $Df(0,0)$. So, again this is an exercise. So, you take the partial derivatives etcetera. So, you get 0 1 minus 1 0.

So, the corresponding linear system, corresponding this is 2. Corresponding linear system is x dot equal to y and y dot equal to minus x . And we have already seen that. So, you have already seen for the linearized linear system linearized system $(0,0)$ is stable, but not at asymptotically stable. And now, we ask the question this $(0,0)$ is it stable for the original system? So, remember this is our original system.

(Refer Slide Time: 36:56)

$Df(0,0) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ The corresponding linear system is
 $\dot{x} = y$
 $\dot{y} = -x$
 $(0,0)$ is stable, but not asymptotically stable.

Consider
 $\frac{d}{dt}(x^2 + y^2) = 2x\dot{x} + 2y\dot{y}$
 $= 2x(y + x(x^2 + y^2)) + 2y(-x + y(x^2 + y^2))$
 $= 2(x^2 + y^2)^2$

So, let us try to analyze in this case directly what will happen. So, consider $\frac{d}{dt}$ of $x^2 + y^2$. So, this again we did in previous example also $x\dot{x} + y\dot{y}$. So, this is just $y + x^3 + y^3$ plus $x^2y + y^2x$ from the original system plus $2y - x + yx^2 + y^2x$. So, this is not asymptotically stable. So, we simply the algebra you get $2(x^2 + y^2)^2$.

(Refer Slide Time: 38:18)

$r^2 = x^2 + y^2, \quad 2r\dot{r} = 2r^3$ or $\dot{r} = r^2$
 $(0,0)$ is unstable for the original system

If we change the signs and consider
 $\dot{x} = y - x(x^2 + y^2)$
 $\dot{y} = -x - y(x^2 + y^2)$
 $(0,0)$ is asymptotically stable for this system

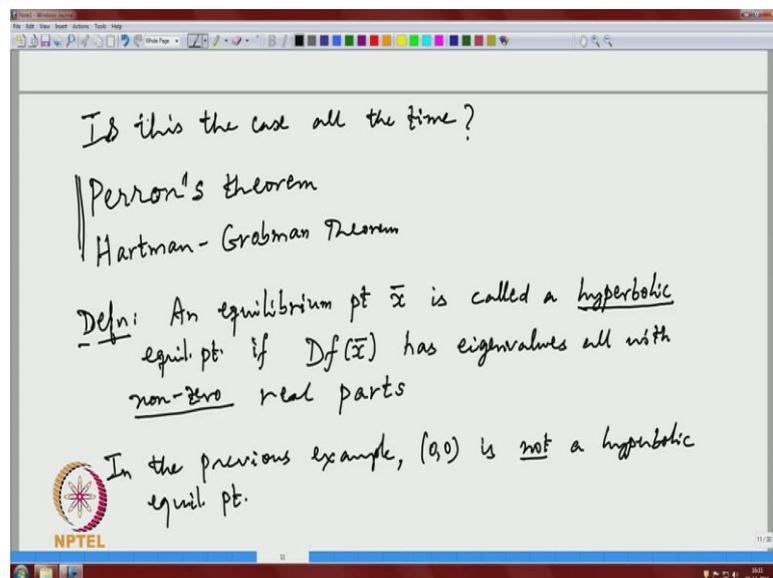

So, if I now call this as r^2 or just r it does not matter. So, if I put $r^2 = x^2 + y^2$ is equal to $x^2 + y^2$. So, the $2r\dot{r}$ is if I do this again. So, this is just r^4 or you get r^3 .

dot is equal to r^3 . So, for this single variable r I get a first order differential equations non-linear that is fine. And that you see this r . So, if r is positive all the time because, we are taking $x^2 + y^2$. So, \dot{r} is r^3 . So, that increases, so always increasing.

So, this the orbits the trajectories go away from the origin. So, you get $(0,0)$ is unstable for the original system. So, the linear analysis says that this origin is stable, but not asymptotically stable. But for the original problem namely this system, the origin is unstable and if you just change the signs. So, if we change the signs. So, this is and consider this system almost same just I change the sign in the non-linear terms.

Again origin is the only equilibrium point and the linearized system does not change and in this case $(0,0)$ is asymptotically stable for this system. So, a linear stability analysis in this example shows, that may not give the correct picture as per as the original system is concerned. And the question is it always the case?

(Refer Slide Time: 41:57)

And then we cannot depend on linear stability analysis at all, if this is the case. Is this the case all the time? That is the question fortunately not. So, there are two results both in the positive directions namely, that whatever linear linearized system predicts the same is true for the non-linear system. So, these two are just mention and we will discuss may be next time. So, these are Perron's Theorem and Hartman Grobman Theorem.

Perron's theorem is very easy to state and even I will try to give a proof of that Hartman Grobman theorem even to state it, I have to develop certain notations. So, I will not go into that thing. But I will just mention what that theorem states. And both these concern a special type of equilibrium points. So, let me define that thing. So, let definition. An equilibrium point \bar{x} is called a hyperbolic equilibrium point, if the Jacobian matrix has Eigen values all with nonzero real parts.

And in this case, if \bar{x} is a hyperbolic equilibrium point. Then whatever happens to the linear system the same thing happens to the non-linear system. And that is the content of this Perron's theorem and Hartman's theorem, Hartman Grobman theorem. So, in the previous example $0\ 0$ is not a hyperbolic equilibrium. And what one should do when \bar{x} is not a hyperbolic point. And that is where Lyapunov comes into picture and Lyapunov develops a beautiful theory called Lyapunov function. And then that is essentially meant for equilibrium points which are not hyperbolic.

(Refer Slide Time: 46:32)

Perron's Theorem Let A be an $n \times n$ real, constant matrix whose eigenvalues all have negative real parts. Suppose $f(t, x)$ is a continuous function s.t. $f(t, x) = o(|x|)$ uniformly in t . Then 0 is asymptotically stable for

$$\dot{x} = Ax + f(t, x)$$

↓
origin is asymptotically stable

NPTEL

So, let me in the remaining time just try to explain what that Perron's theorem is just statement and then. So, this is more general and it is also applicable to more situations even including infinite dimensional cases. So, so let me just try to state it. So, let A be an n by n real constant matrix, whose Eigen values all have negative real part. And in this case you know that, the linear system \dot{x} equal to Ax the origin is asymptotically stable. So, this is one of the cases.

So, suppose so in fact, this Perron's theorem considers a more general perturbations. So, let me just state it. So, $f(x)$ is a continuous function. So, we do not even worry about uniqueness. So, just take the continuous function such that. So, I will explain this a little later. So, I will write a small o of $\|x\|$ uniformly in t . So, this is, so if f does not depend on t then this is fine, but this uniformly in t .

So, this relation, so this is a kind of limit relation, I will write it uniformly in t . Then 0 is asymptotically stable for $\dot{x} = Ax + f(x)$. So, this condition already implies that it is very small for x small. So, this is a small perturbation near the origin. So, if you consider this linear part and the hypothesis that the matrix, the Eigen values of the given matrix all have negative real parts.

So, here the origin is asymptotically stable. And Perron's theorem tells that. So, a small perturbation will not alter the nature of that asymptotic stability. So, even for the non-linear system it will be asymptotically stable and this is one positive result. So, let me may be next time I will give a proof of that. So, let us work out some examples the remaining time.

(Refer Slide Time: 50:56)

The image shows a whiteboard with handwritten mathematical work. At the top, it is titled "Example" and "Duffing Equation (Oscillator)". Below this, it states "2nd order eqn: $\ddot{x} - \alpha x + \beta x^3 + \delta \dot{x} = 0$ ". Then, it says "Put $x = ay$ ". This leads to the equation $a \ddot{y} - \alpha ay + \beta a^3 y^3 + \delta a \dot{y} = 0$. This is simplified to $\ddot{y} - \frac{\alpha}{a} y + \frac{\beta a^2}{a} y^3 + \delta \dot{y} = 0$. A note on the right side of the board specifies $\alpha = \beta a^2$ if $\alpha \beta > 0$ and $-\alpha = \beta a^2$ if $\alpha \beta < 0$. The final result is $\ddot{y} + \alpha (\pm y + y^3) + \delta \dot{y} = 0, \alpha > 0$. The NPTEL logo is visible in the bottom left corner of the whiteboard.

So, let me just start with one example. And try to calculate the linearized system compute this linear system and Eigen values. So, this is Duffing equation. So, you already seen this in the module giving you all the examples and this is also called

Duffing Oscillator. So, it is similar to the mass spring dashpot system. The only thing is here the forcing is non-linear, it is cubic in particular. So, let me just write that.

So, it is second order equation, so $x \ddot{x} - \alpha x + \beta x^3 + \delta \dot{x}$. So, let me consider the unforced one. So, I will put right hand side 0. So, we will also discuss when there is forcing term little later. So, if δ is 0 this can be put in the conservative form that we will study little later. So, when δ is positive, so this describes a dissipative system and we will see the effect of that δ positive.

So, in mathematics all the time what you do is, so there are too many parameters here α β δ , is it possible to remove some of them. And so we do scaling and other things. So, let me also do here. So, that is I did not do for the logistic model. So, let me just do it for this Duffing equation. So, you will learn some scaling argument. So, put y is equal to x equal to $a y$. So, let me put that it is easier.

So, x equal to $a y$ and a is a constant I am going to choose little later. What should be a ? So, if you substitute this x equal to $a y$. So now, y is a new unknown function. So, this the first term will be $a y \ddot{y}$ a is a constant minus $\alpha a y$ plus $\beta a y^3$ plus $\delta a y \dot{y}$. So, I am going to divide by a throughout. So, this implies $y \ddot{y}$ minus αy plus $\beta a^2 y^3$ plus $\delta y \dot{y}$.

Now, I choose my a . So, see here there is α then βa^2 . So, I want to make them equal. So, I choose α is equal to βa^2 and this I can do since a^2 is always positive. This I can do only if α and β have the same sign. So, if $\alpha \beta$ is positive and if $\alpha \beta$ is negative, what I do is I get $\pm \alpha$ if $\alpha \beta$ is. So, in that case what I have is. So, $y \ddot{y}$ I put here plus α . Now, I put plus or minus y plus y^3 0 and α I take to be positive. So, I put plus or minus. So, that is one simplification.

(Refer Slide Time: 56:35)

$$a y'' - \alpha y + \beta^2 y^3 + \delta y = 0$$

$$\Rightarrow y'' - \alpha y + \beta^2 y^3 + \delta y = 0 \quad \begin{cases} \alpha = \beta^2 & \text{if } \alpha > 0 \\ -\alpha = \beta^2 & \text{if } \alpha < 0 \end{cases}$$

$$\Rightarrow y'' + \alpha(+y + y^3) + \delta y = 0, \quad \alpha > 0$$

Put $s = bt$

$$\frac{dy}{dt} = \frac{dy}{ds} \cdot \frac{ds}{dt} = b \frac{dy}{ds}$$

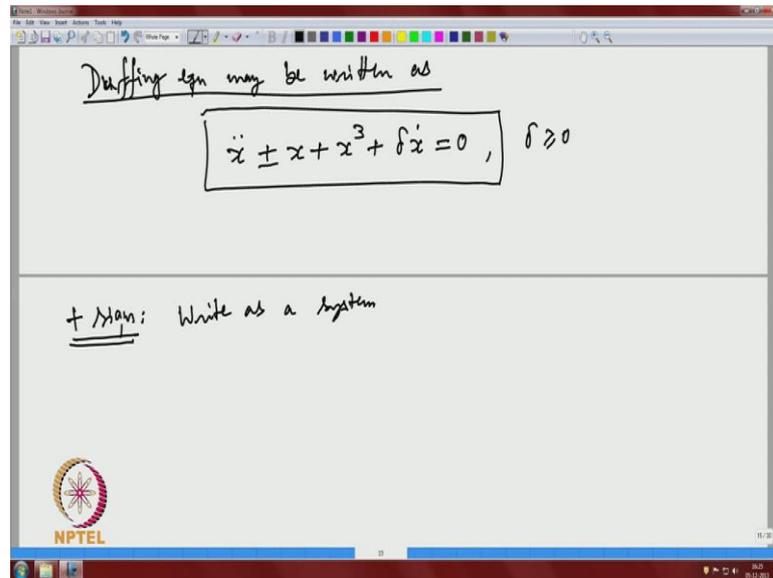

$$b^2 \frac{d^2y}{ds^2} + \alpha(+y + y^3) + \delta b \frac{dy}{ds} = 0 \quad \text{choose } b^2 = \alpha$$

$$\frac{d^2y}{ds^2} + (+y + y^3) + \tilde{\delta} \frac{dy}{ds} = 0$$

And similarly now I can change t . So, put s is equal to $b t$ and now what you get is $d y$ by $d t$ is $d y$ by $d s$ into $d s$ by $d t$ and that is just $b d y$ by $d s$. So, these are scales. So, I am scaling the time variable and I am scaling the unknown function x . So, if you do this thing, again what you get is? So, b square d square y by $d s$ square plus α plus or minus $y y$ cube there is no derivative here. So, that will remain same.

So just, but here I get $\delta b d y$ by $d s$ equal to 0. And again by I divide by b or I choose α equal to b square, choose b square equal to α . And if you do that thing and then you divide by that. So, this will give s square plus plus or minus y plus y cube δ tilde that is $d y$ by $d s$. So, all these exercise.

(Refer Slide Time: 58:30)

Duffing eqn may be written as

$$\ddot{x} \pm x + x^3 + \delta \dot{x} = 0, \quad \delta \geq 0$$

+ Non: write as a system

NPTEL

So, Duffing equation and that is what we are going to do Duffing equation may be written as. So, this is all that exercise. So, again we go back to the original variables plus or minus x plus x cube plus δx dot equal to 0. So, you consider this simplified version. So, let me just go on little bit. So, let me just consider the plus sign. So, let us write it as a system. So, we will continue this linear stability analysis for the Duffing equation in the next class. And we will also see how the theorem of Perron is proved and more examples regarding this linear stability analysis and stability analysis in general.

Thank you.
