First order systems

$$u_t = Au_x \quad t > 0, x \in \mathbb{R} \quad (1)$$

$u = \begin{pmatrix} u_1 \\ \vdots \\ u_N \end{pmatrix}$, $A - N \times N$ real matrix

$$\frac{\partial}{\partial t} u_i = \sum_{j=1}^n a_{ij} \frac{\partial}{\partial x} u_j, \quad i=1,2,\dots,N$$

Assume that A has only real eigenvalues

$A = [a_{ij}]$

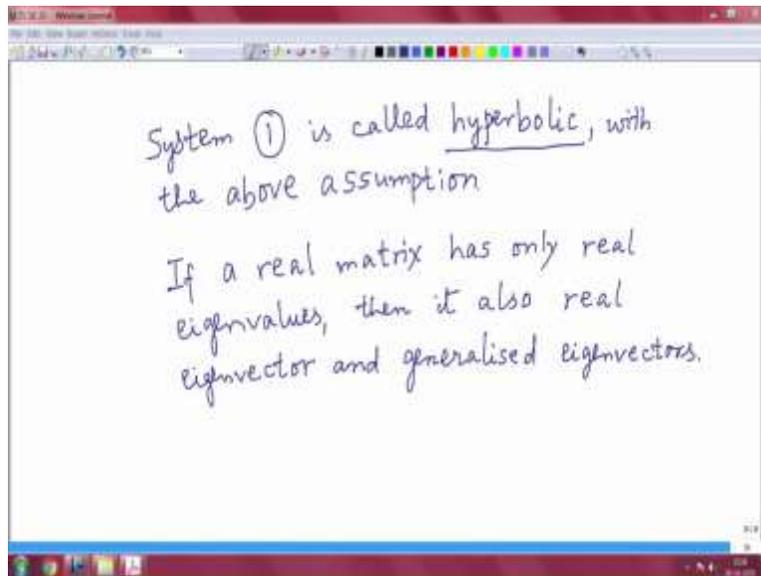

Welcome back. Today, we will continue discussion on some related topics of One D Wave Equation. So briefly discussed first order systems. So now we consider such a system, let me write equal to, so again t is a positive real number and x varies over the real line, so instead of first order system in one space variable.

So here u is a column vector, u_n , and A is N by N real matrix. So if you expand this, so this we have written in matrix notation, if you write component wise, then it is d by dt of u_i is equal to summation j equal to 1 to n a_{ij} , d by dx of u_j . So there are N first order equations, so that is why it is first order system. So a_{ij} are the components of the matrix.

We assume that, so this is basic assumption, assume that A has, the matrix A has only real eigenvalues. As you all know even a real matrix can have complex eigenvalues, so this is an

assumption we are doing on the matrix, given matrix here. With these assumptions, so let me call this system as 1.

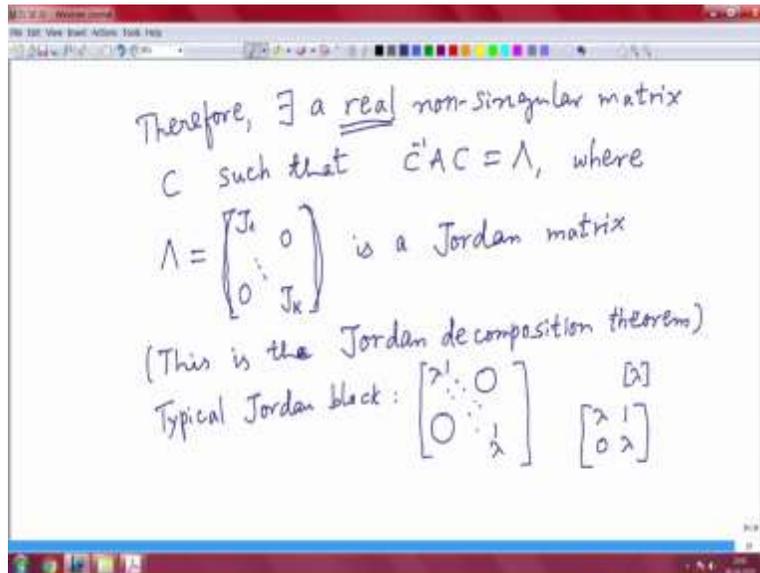

(Refer Slide Time: 4:17)

So system 1 is called hyperbolic, with these assumptions, so that is important with the above assumption. Further classification of system 1 is possible depending on the nature of eigenvalues and the corresponding eigenvectors, that really takes us into some deeper aspects of the theories which I am not going to do. For the purpose just illustrating the applicability of several methods we did in this chapter, I just restrict myself to the case when A has just eigenvalues.

I will not even assume that they are distinct or whatever, just real eigenvalues. In that case again, from linear algebra we learn that, so if a real matrix has, so this is from linear algebra I am recalling, has only real eigenvalues, then it also has real eigenvectors and generalized eigenvectors. So it is good time to recall all these notions from linear algebra, generalized eigenvectors. So that is from linear algebra.

(Refer Slide Time: 7:23)

So therefore, there exists a real non-singular matrix, C such that C inverse AC is Jordan matrix, call it Λ , where Λ , we usually write it as J_1, J_k is a Jordan matrix. So this is the Jordan decomposition theorem. So this is one of the important and very deep theorem of linear algebra. So it is important that with the assumption that A has only real eigenvalues, we are going to get a real non-singular matrix, that is important for us, because we are looking only for the real solutions.

So this J_1, J_2, J_k are Jordan blocks, a typical Jordan block, let me write, typical Jordan block is a square matrix, I am using both, so this is also a matrix notation, so let me just write, square brackets. So on the diagonal you have same Λ and all the elements below the diagonal are 0 and just one on the diagonal, just above the diagonal, sub-diagonal and then again 0, very simple form. It could be 1 by 1, so in that case you have one, just Λ .

So for 2 by 2, so we get $\Lambda 1, 0m$. So these are typical examples, so this is 1 by 1 Jordan block, which is just one element and this is 2 by 2. So what is the advantage of this? The advantage of this is the system 1 reduces to a simpler form which can be easily analyzed.

(Refer Slide Time: 11:31)

Put $v = \bar{C}^{-1} u$ Then,

$$\frac{\partial v}{\partial t} = \bar{C}^{-1} \frac{\partial u}{\partial t} = \bar{C}^{-1} A \frac{\partial u}{\partial x} = \bar{C}^{-1} A C \frac{\partial v}{\partial x} = \Lambda \frac{\partial v}{\partial x}$$

$$\boxed{v_t = \Lambda v_x}$$

$v = \begin{pmatrix} v^{(1)} \\ \vdots \\ v^{(k)} \end{pmatrix}$ according to the orders of $J_i, i=1, \dots, k$

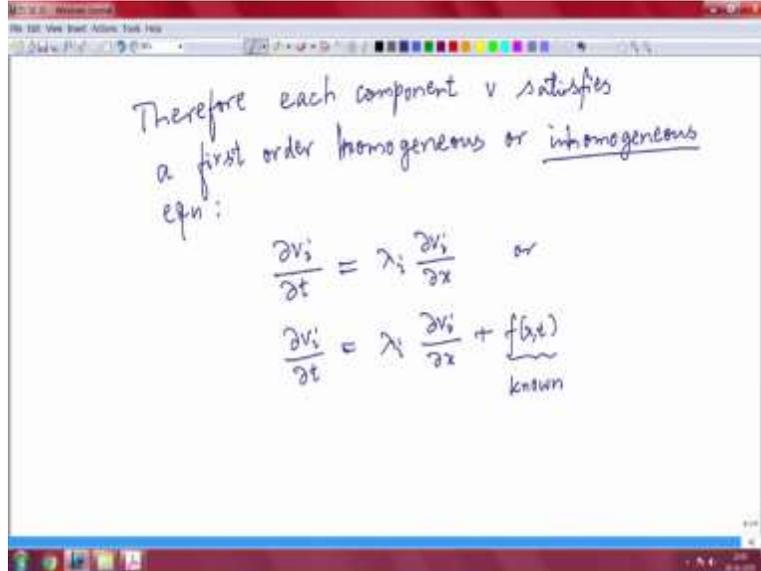

$$\Rightarrow \boxed{\frac{\partial v^{(i)}}{\partial t} = J_i \frac{\partial v^{(i)}}{\partial x}, i=1, 2, \dots, k}$$

So put v is equal to C inverse u . Then let us compute d by dt of v , so since C is constant matrix, so we can just bring it out and use system 1, so this is C inverse, A du by dx . And again, you write in terms of v , so C inverse is C , so u is Cv , so I write it here dv by dx . And this by Jordan decomposition theorem that is expressed as a Jordan matrix, so $del v$ by $del x$.

So this change of variable reduces the system 1 to a simpler form. So namely, so let me again write it, so v_t is v_x . So now if you look at the structure of Λ , so they are all Jordan blocks, so we decompose v as v_1 et cetera v_k according to the orders of the matrixes J_i, i equal to 1. So for example J_1 is 2 by 2, then this v_1 will have two components.

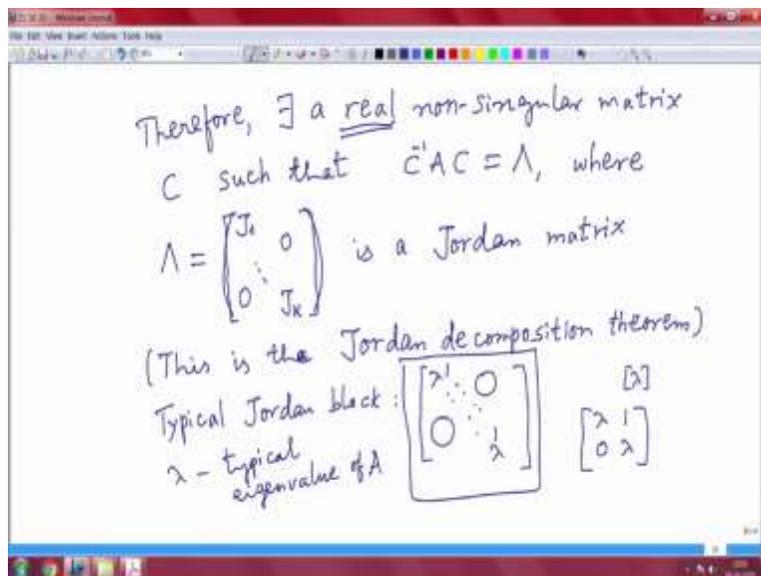

So since this implies, we can write down a system for each of these components, so $del v_i$ by $del t$ is $J_i del v_i$ by $del x$, so i is equal to 1, 2, k . So in this way, we have partially decoupled the system 1 into more or less diagonal, so if for example, A is diagonalizable, then this Λ would be a diagonal matrix and then this will be a completely decoupled system.

(Refer Slide Time: 15:24)

So if we again write, again look at the typical Jordan block, it is of this form, so each component, therefore each component of v satisfies a first order homogeneous or inhomogeneous equation. So let me just write one component v_i , so this $\frac{\partial v_i}{\partial t} = \lambda_i \frac{\partial v_i}{\partial x}$ or $\frac{\partial v_i}{\partial t} = \lambda_i \frac{\partial v_i}{\partial x} + f(x,t)$, no, inhomogeneous. This is a function of x, t , no. So in either case we can just use the method of characteristics and write down the solutions.

(Refer Slide Time: 17:43)

So again, remember, so I did not stress that, so this Lambda's, this Lambda, so this J1, J2, Jk, so each one will look like this, there is Lambda there, so they involve different eigenvalues of Lambda. So Lambda is a typical eigenvalue of A. So they all come there, they all come in the diagonal of this matrix Lambda, so they are all eigenvalues of A.

(Refer Slide Time: 18:40)

Put $v = \underline{C}^{-1} u$ Then,

$$\frac{\partial v}{\partial t} = \underline{C}^{-1} \frac{\partial u}{\partial t} = \underline{C}^{-1} A \frac{\partial u}{\partial x} = \underline{C}^{-1} A \underline{C} \frac{\partial v}{\partial x} = \Lambda \frac{\partial v}{\partial x}$$

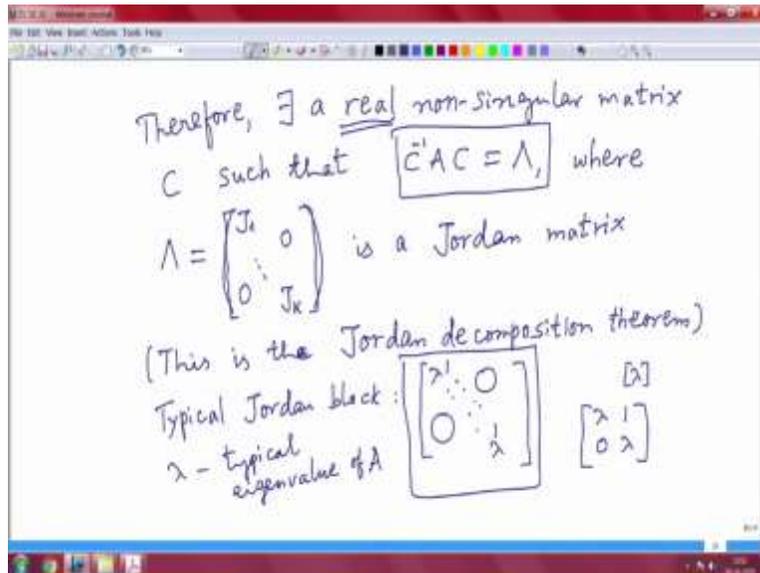

$$\boxed{v_i = \Lambda v_i}$$

according to the orders of $J_i, i=1, \dots, k$

$$\Rightarrow \boxed{\frac{\partial v^{(i)}}{\partial t} = J_i \frac{\partial v^{(i)}}{\partial x}, i=1, 2, \dots, k}$$

So in this context, the eigenvalues in this context the eigenvalues of A play the role of speeds of propagation. Let me now present some examples of various things we did in this one D wave equation.

(Refer Slide Time: 19:56)

So in general, the computation of the matrix C and obtaining this Jordan form is a very difficult task, so it is more or less easily done for 2 by 2 systems, even 3 by 3 systems okay, but once you go beyond third order, then computations become very heavy, but in principle, as far as theory is concerned, it is very nice lifts here and we can decompose the given first order system into more or less a diagonal form.

(Refer Slide Time: 20:53)

Consider the Cauchy problem

$$\square_x v \equiv v_{tt} - c^2 v_{xx} = 0, \quad t > 0, \quad x \in \mathbb{R},$$

with initial conditions

$$v(x, 0) = v_0(x), \quad v_t(x, 0) = v_1(x), \quad x \in \mathbb{R}.$$

If $v_0(x) = x$ and $v_1 \equiv 0$, then the D'Alembert's formula gives the solution $u(x, t) = x$ for all $t > 0$. We may call this a *standing wave* as it does not change with time.

If on the other hand, we take $v_0 \equiv 0$ and $v_1(x) = x$, then the solution is given by $u(x, t) = xt$.

Take the initial values as

$$v_0(x) = \sin x, \quad v_1(x) = \sin x,$$

then the D'Alembert's formula gives the solution as

$$u(x, t) = v_0(x), \quad v_t(x, 0) = v_1(x), \quad x \in \mathbb{R}.$$

If $v_0(x) = x$ and $v_1 \equiv 0$, then the D'Alembert's formula gives the solution $u(x, t) = x$ for all $t > 0$. We may call this a *standing wave* as it does not change with time.

If on the other hand, we take $v_0 \equiv 0$ and $v_1(x) = x$, then the solution is given by $u(x, t) = xt$.

If we take the initial values as

$$v_0(x) = \sin x, \quad v_1(x) = \sin x,$$

then the D'Alembert's formula gives the solution as

$$u(x, t) = \frac{1}{2}(\sin(x+ct) + \sin(x-ct)) + \frac{1}{2c} \int_{x-ct}^{x+ct} \sin \eta \, d\eta$$

So let me show you some examples. So various I have, so let me start with D'Alembert's formula, so this is wave equation we studied this far with given initial data. So here I have taken very simple initial values, for example, if you take u_0 equal to x and u_1 identically 0 and then the D'Alembert's formula give the solution $u(x, t)$ equal to x for all t positive.

So we call this standing wave as it does not change with time, so important here, so in this case it just remains x . So if I now take u_0 identically 0 and u_1 equal to x then the solution is given by xt , x times t . And similarly if you take these as initial values, u_0 and u_1 both $\sin x$, but they are arbitrary, we can take any c_2 function and c_1 function respectively. So here I have just take the simple function, so that we can do the computations easily, that is the only reason.

So you should practice with lots of simple examples where you can integrate easily. So in this case, so D'Alembert's formula gives us $u(x, t)$ equal to $\sin(x + ct) + \sin(x - ct) + \frac{1}{2c} \int_{x-ct}^{x+ct} \eta d\eta$. So if you work out that then you get the solution as $\sin x + \sin x \cos t + c \int \sin x \sin t$.

So you also, I did not mention the inhomogeneous equation here, so you should also try that, so taking instead of 0 you take some $F(x, t)$ where you can integrate it easily and see how the Duhamel's principle works and write down the solution. So this is for the D'Alembert's formula. And then we discussed equations with distinct roots and also multiple roots.

(Refer Slide Time: 23:48)

Equation with multiple characteristics

Let us find the solution of the following third order equation

$$\partial_t(\partial_t - c\partial_x)^2 u = 0, x \in \mathbb{R}, t > 0$$

where $c \neq 0$, with the initial conditions

$$u(x, 0) = u_0(x), u_t(x, 0) = u_1(x) \text{ and } u_{tt}(x, 0) = u_2(x), x \in \mathbb{R}$$

This is an equation with a double characteristic with speed of propagation c and a simple characteristic with 0 speed of propagation.

Put $v = \partial_t u$. Then, v satisfies the equation $(\partial_t - c\partial_x)^2 v = 0$, whose general solution is given by

$$\partial_t u = v = f_1(x + ct) + t f_2(x + ct).$$

An integration with respect to t now gives

This is an equation with a double characteristic with speed of propagation c and a simple characteristic with 0 speed of propagation.

Put $v = \partial_t u$. Then, v satisfies the equation $(\partial_t - c\partial_x)^2 v = 0$, whose general solution is given by

$$\partial_t u = v = f_1(x + ct) + t f_2(x + ct).$$

An integration with respect to t now gives

$$u(x, t) = F_1(x + ct) + t F_2(x + ct) + F_3(x).$$

Using the initial conditions, we obtain the functions F_1 , F_2 and F_3 as follows:

$$\begin{aligned} F_1(x) + F_3(x) &= u_0(x) \\ c F_1'(x) + F_2(x) &= u_1(x) \\ c^2 F_1''(x) + 2c F_2'(x) &= u_2(x). \end{aligned}$$

Solving these equations carefully and plugging in the expression for the solution, we obtain

So here I have taken a simple example of third order equation. So as you see here, so this is a double characteristic part, so $\partial_t^2 u - c \partial_x^2 u = 0$ and here there is only ∂_t . So we can say that one speed of propagation, simple speed of propagation 0 and double characteristic with speed of propagation c , taking c not equal to 0, otherwise it will be just $\partial_t^3 u = 0$, so just an illustration how the solution looks like in comparison with D'Alembert's formula.

So one way of obtaining the solution is substitute, make the substitution v equal $\partial_t u$ and the v satisfies this double characteristic equation and this we have already seen that a general solution

for this second order equation is $F_1 x + ct + t F_2 x + ct$. And that is $\frac{\partial u}{\partial t}$, so we obtained u really is nothing but $\frac{\partial u}{\partial t}$. So now it is only differentiation with respect to t , so we just integrate that.

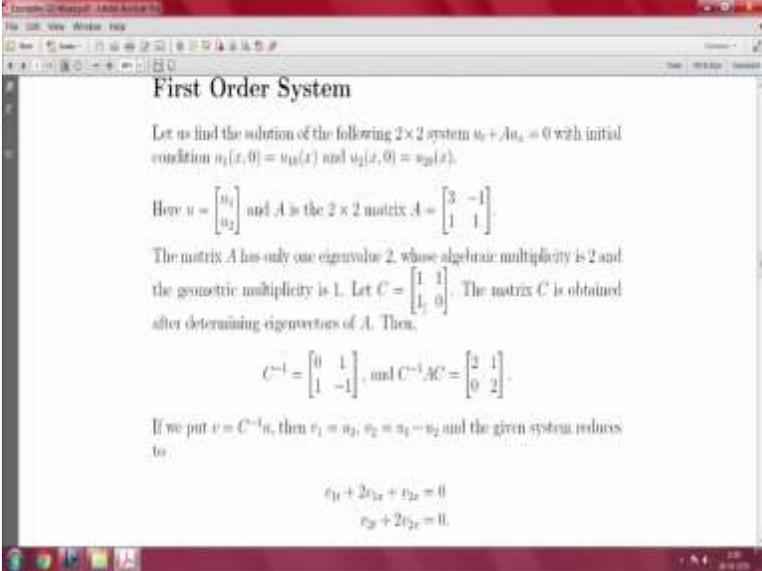

We integrate this $\frac{\partial u}{\partial t}$ equal to this expression and now you realize that this u is given by $F_1 x + ct$, so you integrate only with respect to t , so x remains the same. And this $F_3 x$ is added because that is constant as far as t derivative is concerned. So instead of just a constant we can add a function of x because it is differentiation with respect to t .

And now you plug in the given initial data, so $u(x, 0) = u_0(x)$, the first derivative with respect to t at x_0 is u_x and x and second derivative with respect to t is u_{tt} , and if the substitute in this general formula, general expression of the solution, then we get three equations. They are simple, linear but you have to really be careful in determining this F_1, F_2, F_3 .

And once you determine F_1, F_2, F_3 you plug in, in this general expression. So I have left several steps for you to work out and this is the final solution of that equation. So you see that because of this double characteristic nature of the equation, we require more smoothness of the initial condition in order to obtain less differentiable solution.

Again, loss of regularity, so we require u_0 and u_2 to be C^2 functions, whereas u_1 is required to be a C^3 function, and then the solution has required smoothness namely twice differentiable with respect to x and thrice differentiable with respect to t , so remember here, the equation. So we require u to be differentiable with respect to t three times and with respect to x only two times.

(Refer Slide Time: 28:23)

First Order System

Let us find the solution of the following 2×2 system $u_t + Au_t = 0$ with initial condition $u_1(x, 0) = u_{10}(x)$ and $u_2(x, 0) = u_{20}(x)$.

Here $u = \begin{bmatrix} u_1 \\ u_2 \end{bmatrix}$ and A is the 2×2 matrix $A = \begin{bmatrix} 3 & -1 \\ 1 & 1 \end{bmatrix}$.

The matrix A has only one eigenvalue 2, whose algebraic multiplicity is 2 and the geometric multiplicity is 1. Let $C = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}$. The matrix C is obtained after determining eigenvectors of A . Then,

$$C^{-1} = \begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}, \text{ and } C^{-1}AC = \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix}.$$

If we put $v = C^{-1}u$, then $v_1 = u_1$, $v_2 = u_1 - u_2$ and the given system reduces to

$$\begin{aligned} v_{1t} + 2v_{1x} + v_{2x} &= 0 \\ v_{2t} + 2v_{2x} &= 0. \end{aligned}$$

Let us find the solution of the following 2×2 system $u_t + Au_t = 0$ with initial condition $u_1(x, 0) = u_{10}(x)$ and $u_2(x, 0) = u_{20}(x)$.

Here $u = \begin{bmatrix} u_1 \\ u_2 \end{bmatrix}$ and A is the 2×2 matrix $A = \begin{bmatrix} 3 & -1 \\ 1 & 1 \end{bmatrix}$.

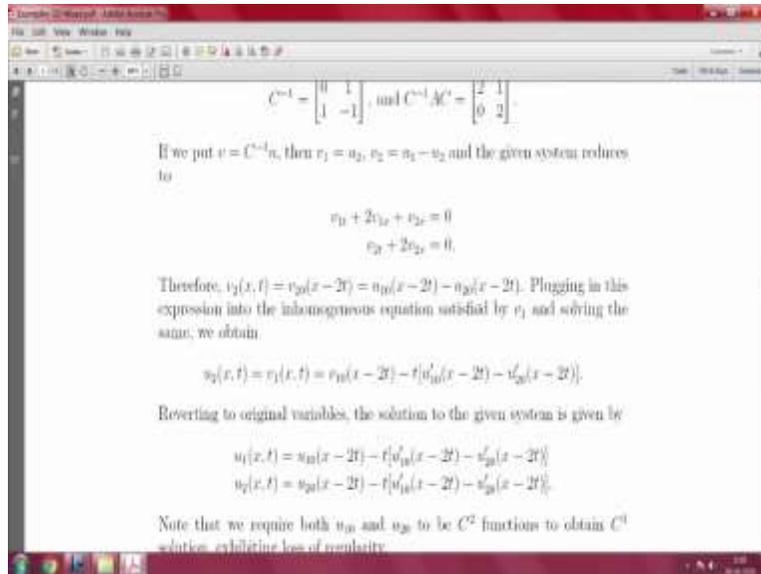

The matrix A has only one eigenvalue 2, whose algebraic multiplicity is 2 and the geometric multiplicity is 1. Let $C = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}$. The matrix C is obtained after determining eigenvectors of A . Then,

$$C^{-1} = \begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}, \text{ and } C^{-1}AC = \begin{bmatrix} 2 & 1 \\ 0 & 2 \end{bmatrix}.$$

If we put $v = C^{-1}u$, then $v_1 = u_1$, $v_2 = u_1 - u_2$ and the given system reduces to

$$\begin{aligned} v_{1t} + 2v_{1x} + v_{2x} &= 0 \\ v_{2t} + 2v_{2x} &= 0. \end{aligned}$$

Therefore, $v_1(x, t) = v_{20}(x - 2t) = u_{10}(x - 2t) - u_{20}(x - 2t)$. Plugging in this

And just now we discussed the first order system, so here I have taken a simple 2 by 2 system. So here matrix is 3 minus 1, 1, 1, A has only one real eigenvalue 2, so that is real eigenvalue, so this equation is hyperbolic, whose algebraic multiplicity is 2 and geometric multiplicity is 1 and let us see this matrix. So this computation of the C how you obtain C, you have to work out the eigenvectors and generalized eigenvectors.

And then we get C inverse AC is just this Jordan block, 2, 2, 1, 0. And now as we did so we write the v equal to C inverse u and so the two components of v1, v2 of v they satisfy these two equations. So equation for v2 is a first order equation, which is homogeneous, whereas for v1 it is inhomogeneous where v2 appears as inhomogeneous term.

But v2 determined by the second equation, so that v2 is norm. So, if you work out again by method of characteristics, so I have written here the final solution.

(Refer Slide Time: 30:00)

of caution in using this method.

$$\left. \begin{aligned} u_{tt} - c^2 u_{xx} &= 0, \quad 0 < x < L, \quad t > 0 \\ u(x, 0) &= \varphi(x), \quad u_t(x, 0) = 0, \quad 0 \leq x \leq L \\ u(0, t) &= u(L, t) = 0, \quad t > 0. \end{aligned} \right\}$$

Here $L > 0$ and the function φ is given by $\varphi(x) = \frac{4u_0}{L} [L - |L - 2x|]$, $x \in [0, L]$, u_0 is a constant. Physically, the problem describes the vibrations of a string tied at the ends $x = 0$ and $x = L$ and, initially, plucked in the middle to u_0 . See the figure.

Let me just complete with one Fourier method, so this is taken again a simple example here, so wave equation in a finite interval with initial conditions on the interval $0L$ and then boundary conditions on x equal to 0 and x equal to L . So here I have taken this, so physically, this describes the motion of a string which is tied at the ends, 0 and L , so here it is 0 and L and plugged in the middle to a distance of u_0 , it can be below or above, so I have just drawn here a typical method separation of variables follows.

(Refer Slide Time: 30:59)

for $k = 0, 1, 2, \dots$. Therefore,

$$u(x, t) = \frac{4u_0}{\pi^2} \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)^2} \sin\left(\frac{(2k+1)\pi x}{L}\right) \cos\left(\frac{(2k+1)\pi t}{L}\right).$$

Note that the justification of term-by-term differentiation for the second derivatives is not possible. Thus, we cannot claim that u is a C^2 solution. In fact, if we require that u is a C^2 solution, then sufficient conditions on the initial conditions $u|_{t=0} = \phi$ and $u_t|_{t=0} = \psi$ are that $\phi \in C^3$ and $\psi \in C^3$. In the present case ϕ is not differentiable at $x = L/2$ and its second derivative is a Dirac function.

So if you work out, so just look at the work out here. so my comment will be on the final solution. So if you work out in this particular case, so we have to do some hard integrals here, they are not so hard, but still one has to work out and the final solution in this case, you get this.

So remark is that u is not a C^2 solutions, so this is limitation of the separation of variable method, so though a nice looking formula we cannot claim that u is a C^2 function, because generally in this infinite series we rely on term by term differentiation and if u is C^1 , that is no problem, because if you differentiate once, so still there is one factor left here $2k + 1$ and that makes that summation conversion.

But when you take the second derivative term by term differentiation, this $2k + 1$ square vanishes completely, so we are just left with \sin and $\cos \sin$, and that we cannot make out whether convergent or not and it is not. So u is not a C^2 solution. So in general, you require more smoothness on the initial conditions in order that the separation of variable methods works.

So you should keep this mind whereas the D'Alembert's formula and similar things we described yesterday, so they do not more smoothness, but of course we cannot obtain a solution in a closed form. That is the drawback there, but the drawback here is this one. So, with this I conclude this chapter on one dimensional wave equations.

So in these few lectures we have covered some aspects of one d wave equation. So in such a short span it is not possible to cover all the aspects of even one d wave equation, but since we would like to show you all the important equations, namely equations, Laplace equation and heat equation. So we will do these things in more detail maybe in a next course. Thank you.
