Generalized inverse of matrices

(Refer Slide Time: 0:19)

Also, $\| (A-B)x \|_2 \leq \| A-B \|_2 \| x \|_2$
 $\Rightarrow \| A-B \|_2^2 \geq \sum_{i=1}^{k+1} |v_i^H x|^2 \sigma_i^2 \geq \sigma_{k+1}^2 \Rightarrow \| A-B \|_2 \geq \sigma_{k+1}$
 because of the ordering of σ_i and since $\sum_{i=1}^{k+1} |v_i^H x|^2 = 1$. \square

Generalized inverses of matrices: $A \in \mathbb{C}^{m \times n}$.

Defn. The generalized inverse of A is the unique matrix $B \in \mathbb{C}^{n \times m}$ satisfying

- (i) AB is hermitian, i.e., $AB = (AB)^H = B^H A^H$
- (ii) BA is hermitian, i.e., $BA = (BA)^H = A^H B^H$
- (iii) $ABA = A$
- (iv) $BAB = B$.

Called the Moore-Penrose pseudoinverse or generalized inverse.
 Often, denoted by A^\dagger .

Generalized inverses of matrices: $A \in \mathbb{C}^{m \times n}$.

Defn. The generalized inverse of A is the unique matrix $B \in \mathbb{C}^{n \times m}$ satisfying

- (i) AB is hermitian, i.e., $AB = (AB)^H = B^H A^H$
- (ii) BA is hermitian, i.e., $BA = (BA)^H = A^H B^H$
- (iii) $ABA = A$
- (iv) $BAB = B$.

Called the Moore-Penrose pseudoinverse or generalized inverse.
 Often, denoted by A^\dagger .

Prop. Let $A \in \mathbb{C}^{m \times n}$. Then \exists a unique $B \in \mathbb{C}^{n \times m}$

So, the next topic is generalized inverses of matrices. So we know that if a matrix is square and non singular, we can always invert it. But in order to solve systems of linear equations and even for many other problems, we will need to invert matrices that are rectangular of size m by n . So,

for that we use this concept of generalized inverses. And these generalized inverses have various properties that we can also study.

So, we will start with the basic definition, the generalized inverse of a matrix A size m by n is the unique matrix B of size n by m . So, note that the dimensions are reversed, it is of size n by m , satisfying four properties. The first property is that AB is a Hermitian symmetric matrix, that is AB equals AB Hermitian, which, of course is B Hermitian A Hermitian.

Similarly, BA is a Hermitian matrix that is BA is equal to BA Hermitian, which is equal to A Hermitian B Hermitian. Then, A times B times A equals A , B times A times B equals B . So, the matrix B that satisfies these four properties is a unique matrix and is called the generalized inverse or the Moore Penrose pseudo inverse of this matrix A , can be often denoted by A dagger. So, the fact that this is a unique matrix that satisfies all these four properties is the essence of this proposition.

(Refer Slide Time: 2:02)

Generalized inverses of matrices: $A \in \mathbb{C}^{m \times n}$.

Defn. The generalized inverse of A is the unique matrix $B \in \mathbb{C}^{n \times m}$ satisfying

- (i) AB is hermitian, i.e., $AB = (AB)^H = B^H A^H$
- (ii) BA is hermitian, i.e., $BA = (BA)^H = A^H B^H$
- (iii) $ABA = A$
- (iv) $BAB = B$.

Called the Moore-Penrose pseudoinverse or generalized inverse, often, denoted by A^\dagger .

Prop. Let $A \in \mathbb{C}^{m \times n}$. Then \exists a unique $B \in \mathbb{C}^{n \times m}$ satisfying (i)-(iv).

Proof: Let $A \in U \Sigma V^H$ be the SVD of A .

the top

NPTEL

(ii) BA is hermitian, i.e., $BA = (BA)^H = A^H B^H$
 (iii) $ABA = A$
 (iv) $BAB = B$.

Called the Moore-Penrose pseudoinverse or generalized inverse.
 Often, denoted by A^+ .

Prop. Let $A \in \mathbb{C}^{m \times n}$. Then \exists a unique $B \in \mathbb{C}^{n \times m}$
 satisfying (i)-(iv).

Proof: Let $A \in U \Sigma V^H$ be the SVD of A .
 (Existence): Σ has an $r \times r$ diag. block D in the top
 left, where $r = \text{rank}(A)$.
 Let Σ_1 be an $n \times m$ matrix with D^{-1} in the top left
 $r \times r$ block.

NPTEL

Generalized inverses of matrices: $A \in \mathbb{C}^{m \times n}$.

Defn. The generalized inverse of A is the unique matrix $B \in \mathbb{C}^{n \times m}$
 satisfying

(i) AB is hermitian, i.e., $AB = (AB)^H = B^H A^H$
 (ii) BA is hermitian, i.e., $BA = (BA)^H = A^H B^H$
 (iii) $ABA = A$
 (iv) $BAB = B$.

Called the Moore-Penrose pseudoinverse or generalized inverse.
 Often, denoted by A^+ .

Prop. Let $A \in \mathbb{C}^{m \times n}$. Then \exists a unique $B \in \mathbb{C}^{n \times m}$
 satisfying (i)-(iv).

Proof: Let $A \in U \Sigma V^H$ be the SVD of A .
 (Existence): Σ has an $r \times r$ diag. block D in the top
 left, where $r = \text{rank}(A)$.
 Let Σ_1 be an $n \times m$ matrix with D^{-1} in the top left
 $r \times r$ block.

So, let A be a matrix of size m by n , then there exists a unique matrix B , which satisfies 1 to 4. So, what is saying, it is in fact saying two things. One is that it is always possible to satisfy these properties 1 to 4. And there is only one matrix that satisfies all four of these properties, very interesting proposition.

So, in other words, you can find a pseudo inverse for any matrix A , no exceptions. And that pseudo inverse that you find there is no other one. It is a unique one. So here is how the proof goes. So again, we start with the singular value decomposition of the matrix A u sigma v Hermitian.

So first, we will talk about existence that is to show that there exists a matrix B , which satisfies these four properties.

Student questioning: Sir.

Professor: Go ahead.

Student: Sir, that mean that any $(n \times m)$ is a square matrix of not full rank, there exist this pseudo $(n \times m)$ inverse?

Professor: Can you repeat your question?

Student: If A is a square matrix of rank lesser than full rank, I mean, not full rank. Does pseudo inverse exist for that also?

Professor: Always.

Student: Okay, thank you.

Professor: Yeah. So you can find a pseudo inverse of any matrix square, rectangle, anything. It always exists, and it is unique. You cannot find two of them. It is a very intriguing property.

Student: Sir one more question.

Professor: Yeah.

Student: Does the pseudo inverse equal to inverse?

Professor: Yes. So we will see that actually, that when, if the matrix A is square and invertible, the pseudo inverse equals the inverse. In fact, we can see something about that right away. Suppose A was a square matrix, and it was invertible. And if B was equal to A inverse, then if I take AB , AB is the identity matrix.

Yes, of course, it is Hermitian. Similarly, BA is the identity matrix. Of course it is Hermitian. If I do ABA , that BA cancel with each other, and I will be left with A , if I do BAB , AB cancel with each other, I will be left with B . So the normal inverse also satisfies all these four properties when A is square and invertible, that is the reason why it is called a generalized inverse, it is not

telling you something new when you go to square matrices that are invertible, it is the same inverse that you will get if you were to invert the matrix.

(Refer Slide Time: 5:15)

(iv) $BAB = B$.

Called the Moore-Penrose pseudoinverse or generalized inverse often, denoted by A^+ .

Prop. Let $A \in \mathbb{C}^{m \times n}$. Then \exists a unique $B \in \mathbb{C}^{n \times m}$ satisfying (i)-(iv).

Proof: Let $A \in U \Sigma V^H$ be the SVD of A .

(Existence): Σ has an $r \times r$ diag. block D in the top left, where $r = \text{rank}(A)$. Σ is of size $m \times n$.

Let Σ_1 be an $n \times m$ matrix with D^{-1} in the top left $r \times r$ block and zeros everywhere else.

Now, $\Sigma \Sigma_1 = \Sigma^H \Sigma^H$

Proof: Let $A \in U \Sigma V^H$ be the SVD of A .

(Existence): Σ has an $r \times r$ diag. block D in the top left, where $r = \text{rank}(A)$. Σ is of size $m \times n$.

Let Σ_1 be an $n \times m$ matrix with D^{-1} in the top left $r \times r$ block and zeros everywhere else.

Now, $\Sigma \Sigma_1 = \Sigma_1^H \Sigma_1^H$

$$\begin{bmatrix} D & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} D^{-1} & 0 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}$$

$\Sigma \quad \Sigma_1 \quad \Sigma_1^H \quad \Sigma^H$

$\Sigma_1 \Sigma = \Sigma$

$\Sigma_1 \Sigma \Sigma_1 = \Sigma_1$

$\Rightarrow \Sigma_1$ is an M-P pseudo of Σ .

Let $B = \dots$ check that B satisfies (i)-(iv)

So, this sigma here has an r cross r diagonal block D in the top left, where r is equal to the rank of A . So that is our standard SVD. Let sigma 1 be an n by m matrix, with D inverse in the top left r cross r blocks and everywhere, 0 s everywhere else. So, this is of size m by n . And sigma 1 is of size n by m . So, the opposite size. What we will first show is that sigma 1 is the Moore Penrose pseudo inverse of sigma.

So, if I take $\Sigma \Sigma^\dagger$. That is equal to Σ^\dagger , so this you just have to write it out what it looks like. So, this will be like a D with 0, 0, 0 here, and then this Σ^\dagger will be D inverse. These 0s are all of different dimensions, this is a size n by m , this is a size n by n . And so I will get the identity and 0, 0s. And that is exactly equal to Σ^\dagger Hermitian times Σ Hermitian, which is to say that the Hermitian of this matrix is equal to itself.

So, $\Sigma \Sigma^\dagger$ is Hermitian so it satisfies property 1, $\Sigma^\dagger \Sigma$ is equal to Σ^\dagger Hermitian Σ^\dagger Hermitian. So, this also satisfies that this matrix is a Hermitian symmetric matrix, $\Sigma \Sigma^\dagger \Sigma = \Sigma$. So, I will just write this like this, sorry. This is actually a bad way to write it, because this is Σ , this is Σ^\dagger , this is Σ^\dagger Hermitian. And this is Σ Hermitian. So, they are all of different dimensions, but you have, so, basically the 0s are all of different dimensions, but by just matching up the dimensions, you can verify that this is actually true.

And similarly, $\Sigma \Sigma^\dagger \Sigma = \Sigma$ and $\Sigma^\dagger \Sigma \Sigma^\dagger = \Sigma^\dagger$. So, basically Σ^\dagger is the more Penrose, for now, since I have not said shown uniqueness, I can say that it is an more Penrose inverse of Σ .

Student: Sir, is he the Penrose who got the Nobel price?

(Refer Slide Time: 8:48)

Let Σ_1 be an $n \times m$ matrix with r $r \times r$ block and zeros everywhere else.

Now, $\Sigma \Sigma_1 = \Sigma_1^H \Sigma^H$

$\Sigma_1 \Sigma = \Sigma_1^H \Sigma^H$

$\Sigma \Sigma_1 \Sigma = \Sigma$

$\Sigma_1 \Sigma \Sigma_1 = \Sigma_1$

$\Rightarrow \Sigma_1$ is an M-P pseudoinverse of Σ .

$A = U \Sigma V^H$

Let $B = V \Sigma_1 U^H$. Then, can easily check that B satisfies (i)-(ii)

(i) $AB = U \Sigma V^H V \Sigma_1 U^H = U \Sigma \Sigma_1 U^H = U \Sigma_1^H \Sigma^H U^H$

$= U \Sigma_1^H V^H V \Sigma^H U^H = (V \Sigma_1 U^H)^H (U \Sigma V^H)^H = B^H A^H$

Similarly

Professor: So, coming back to, coming back to our proof. Suppose B , now okay, so let us define B to be v times Σ^{-1} times u^H Hermitian. So, what is B ? If I have the SVD of A , I will write it here A is equal to $u \Sigma v^H$ Hermitian. All I have done is to take the nonzero r cross r block in Σ , invert that and put that as a matrix Σ^{-1} of size n by m pre multiplied by v post multiplied by u^H Hermitian. Interesting matrix, it is easy to obtain once you have the singular value decomposition of A .

Then we can easily check that B satisfies properties 1 through 4. That is, for example, if you look at AB that is $u \Sigma v^H v \Sigma^{-1} u^H$ Hermitian, just substituting for A and B , but we $v^H v$ is the identity matrix. So it is $u \Sigma \Sigma^{-1} u^H$ Hermitian and $\Sigma \Sigma^{-1}$ is equal to $\Sigma^{-1} \Sigma$ Hermitian. So, it is $u \Sigma^{-1} u^H$ Hermitian, Σ Hermitian times u^H Hermitian.

And now I can re insert a $v^H v$ Hermitian v in between these two matrices and write it as $u \Sigma^{-1} u^H v^H v \Sigma^{-1} u^H$ Hermitian, $v^H v$ is the identity matrix. And this itself is basically B Hermitian, if B is this then B Hermitian is $u \Sigma^{-1} u^H$ Hermitian times $v^H v$ Hermitian. So, that is B Hermitian and this quantity here is just A Hermitian, A is $u \Sigma v^H$ Hermitian. So, A Hermitian would be $v \Sigma u^H$ Hermitian. So, this is equal to B Hermitian A Hermitian which is the same as AB whole Hermitian.

So, AB is a Hermitian symmetric matrix, in a similar way you can verify properties 2, 3, 4. And so, this matrix B that we defined here it satisfies the four properties required by the Moore Penrose pseudo inverse.

(Refer Slide Time: 11:01)

$\Sigma_1 \Sigma = \Sigma_1^H \Sigma_1^H$
 $\Sigma \Sigma_1 \Sigma = \Sigma$
 $\Sigma_1 \Sigma \Sigma_1 = \Sigma_1$

$\Rightarrow \Sigma_1$ is an H-P pseudoinverse of Σ .
 $A = U \Sigma V^H$

Let $B = V \Sigma_1 U^H$. Then, can easily check that B satisfies (i)-(ii)

(i) $AB = U \Sigma V^H V \Sigma_1 U^H = U \Sigma \Sigma_1 U^H = U \Sigma_1^H \Sigma^H U^H$
 $= U \Sigma_1^H V^H V \Sigma^H U^H = (V \Sigma_1 U^H)^H (U \Sigma V^H)^H = B^H A^H$

Similarly check (ii)-(iv). (Exercise).

Uniqueness: Suppose matrices B_1 & B_2 satisfy (i)-(iv).
 Then $(B_1^H - B_2^H) = B_1^H A^H B_1 - B_2^H A^H B_2 = A B_1 B_1^H - A B_2 B_2^H$
 (using (i))

$AB = U \Sigma V^H V \Sigma_1 U^H = U \Sigma \Sigma_1 U^H = U \Sigma_1^H \Sigma^H U^H$
 $= U \Sigma_1^H V^H V \Sigma^H U^H = (V \Sigma_1 U^H)^H (U \Sigma V^H)^H = B^H A^H$

Similarly check (ii)-(iv). (Exercise).

Uniqueness: Suppose matrices B_1 & B_2 satisfy (i)-(iv).
 Then $(B_1^H - B_2^H) = B_1^H A^H B_1 - B_2^H A^H B_2 = A B_1 B_1^H - A B_2 B_2^H$
 (using (i))

$\Rightarrow \mathcal{R}(B_1^H - B_2^H) \subset \mathcal{R}(A)$

$B_1^H A B_1^H = B_1^H$
 $A B_1 = B_1^H A^H$

Also, $AA^H (B_1^H - B_2^H) = A B_1 A - A B_2 A = A - A = 0$
 (using (i) & (iii))

$\Rightarrow \mathcal{R}(B_1^H - B_2^H) \subset \mathcal{N}(AA^H)$.

Now, $AA^H \mathcal{R}(B_1^H - B_2^H) = 0$.

Generalized inverses of matrices: $A \in \mathbb{C}^{m \times n}$.

Defn. The generalized inverse of A is the unique matrix $B \in \mathbb{C}^{n \times m}$ satisfying

- (i) AB is hermitian, i.e., $AB = (AB)^H = B^H A^H$
- (ii) BA is hermitian, i.e., $BA = (BA)^H = A^H B^H$
- (iii) $ABA = A$
- (iv) $BAB = B$.

Called the Moore-Penrose pseudoinverse or generalized inverse. Often, denoted by A^\dagger .

Prop. Let $A \in \mathbb{C}^{m \times n}$. Then \exists a unique $B \in \mathbb{C}^{n \times m}$ satisfying (i)-(iv).

Proof: Let $A \in U\Sigma V^H$ be the SVD of A .

So, we now know that there exists a Moore Penrose pseudo inverse. Now, the uniqueness is a little more complex. So, suppose there are two different matrices B_1 and B_2 that satisfy all four properties, 1 to 4. Then if I look at B_1 Hermitian minus B_2 Hermitian that is the same as B_1 equals $B_1 AB_1$.

So, for example, we know that so if I take the Hermitian so B_1 Hermitian is same as $B_1 A B_1$ Hermitian. So, B_1 Hermitian is $B_1 A B_1$ Hermitian, so B_1 Hermitian $A B_1$ Hermitian minus B_2 Hermitian $A B_2$ Hermitian So, that is the difference between B_1 Hermitian and B_2 Hermitian. But by property one AB is equal to B Hermitian A Hermitian.

So, I have B_1 Hermitian A Hermitian which is equal to AB_1 . So, $A B_1 B_1$ Hermitian minus $A B_2$ similarly, for this $A B_2 B_2$ Hermitian. So, this difference is equal to $A B_1 B_1$ Hermitian minus $A B_2 B_2$ Hermitian. So, you can see that this is equal to A times $B_1 B_1$ Hermitian minus $B_2 B_2$ Hermitian.

So, the range space of B_1 minus, B_1 Hermitian minus B_2 Hermitian is a subset of the range space of A because you can write it as A times some matrix, so, it will have to these columns will have to lie in the column space of A . Similarly, using these properties 1 and 3, if you look at AA Hermitian times B_1 Hermitian minus B_2 Hermitian you can write this as $AB_1 A$ minus $AB_2 A$, but $AB_1 A$ equals A and $AB_2 A$ equals A . And so, that is A minus A which is 0 matrix.

And so, what that means is the range space of B_1 minus B_2 , any vector belonging to the column space of this matrix will lie in the null space of AA^H Hermitian. So, this span of B_1 Hermitian minus B_2 Hermitian lies in the range space of A , it also lies in the null space of AA^H Hermitian.

(Refer Slide Time: 14:19)

Similarly check (ii)-(iv), (exercise).

Uniqueness: Suppose matrices B_1 & B_2 satisfy (i)-(iv)

$$\text{Then } (B_1^H - B_2^H) = B_1^H A^H B_1 - B_2^H A^H B_2 = AB_1 B_1^H - AB_2 B_2^H$$

(using (i))

$$\Rightarrow R(B_1^H - B_2^H) \subset R(A)$$

$B_1^H A^H B_1 = B_1^H$
 $A B_1 = B_1 A$

$$\text{Also, } AA^H (B_1^H - B_2^H) = AB_1 A - AB_2 A = A - A = 0$$

(using (i) & (iii))

$$\Rightarrow R(B_1^H - B_2^H) \subset N(AA^H).$$

Now, $AA^H v = 0 \Rightarrow B_1 AA^H v = 0$.

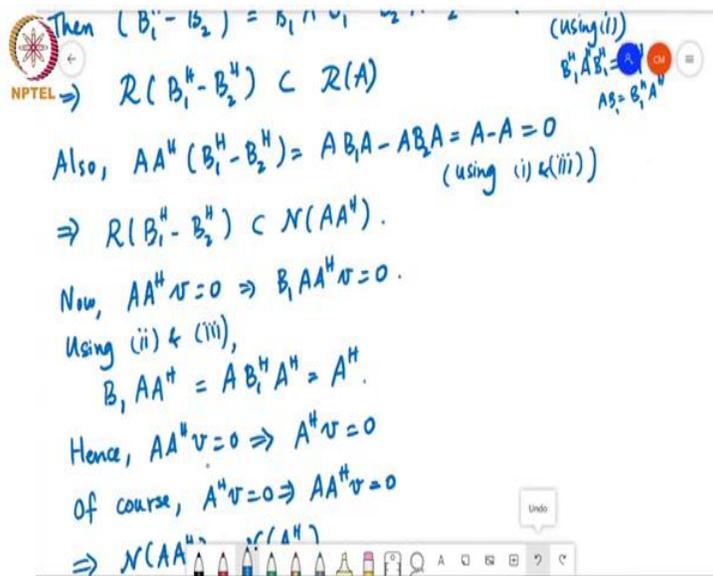

Using (ii) & (iii),

$$B_1 AA^H = AB_1^H A^H = A^H.$$

Hence, $AA^H v = 0$

Now, if a vector lies in the null space of AA^H Hermitian that means $AA^H v = 0$, which then means that just B_1 multiplying by B_1 , B_1 times $AA^H v = 0$. Now, you should verify this, that again I am just repeatedly using these properties. It means that I mean this, these properties mean that if I look at $B_1 AA^H$, this matrix here that is the same as $AB_1^H A^H$ times A^H , which is equal to A^H .

(Refer Slide Time: 14:57)

Then $(B_1^H - B_2^H) = B_1^H v_1 - B_2^H v_2 \dots$ (using (i))

$\Rightarrow R(B_1^H - B_2^H) \subset R(A)$

Also, $AA^H(B_1^H - B_2^H) = AB_1A - AB_2A = A - A = 0$
(using (i) & (iii))

$\Rightarrow R(B_1^H - B_2^H) \subset N(AA^H)$.

Now, $AA^H v = 0 \Rightarrow B_1 AA^H v = 0$.

Using (ii) & (iii),
 $B_1 AA^H = AB_1^H A^H = A^H$.

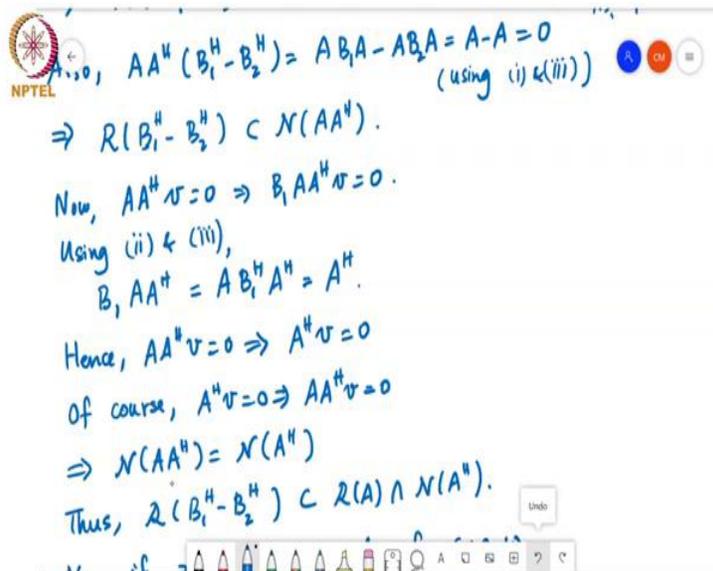

Hence, $AA^H v = 0 \Rightarrow A^H v = 0$

Of course, $A^H v = 0 \Rightarrow AA^H v = 0$

$\Rightarrow N(AA^H) = N(A^H)$

So, $AA^H v = 0$ then implies that $A^H v = 0$.

(Refer Slide Time: 15:15)

Also, $AA^H(B_1^H - B_2^H) = AB_1A - AB_2A = A - A = 0$
(using (i) & (iii))

$\Rightarrow R(B_1^H - B_2^H) \subset N(AA^H)$.

Now, $AA^H v = 0 \Rightarrow B_1 AA^H v = 0$.

Using (ii) & (iii),
 $B_1 AA^H = AB_1^H A^H = A^H$.

Hence, $AA^H v = 0 \Rightarrow A^H v = 0$

Of course, $A^H v = 0 \Rightarrow AA^H v = 0$

$\Rightarrow N(AA^H) = N(A^H)$

Thus, $R(B_1^H - B_2^H) \subset R(A) \cap N(A^H)$.

So, that means that the null space of AA^H is equal to the null space of A^H itself. Almost done.

(Refer Slide Time: 15:27)

Using (1),
 $AA^H = A B_1^H A^H = A^H$.

Hence, $AA^H v = 0 \Rightarrow A^H v = 0$

Of course, $A^H v = 0 \Rightarrow AA^H v = 0$

$\Rightarrow N(AA^H) = N(A^H)$

Thus, $\mathcal{R}(B_1^H - B_2^H) \subset \mathcal{R}(A) \cap N(A^H)$.

Now, if $z \in \mathcal{R}(A)$, $z = Aw$ for some w .

$z \in N(A^H) \Rightarrow A^H z = 0 \Rightarrow A^H A w = 0$

$\Rightarrow w^H A^H A w = 0 \Rightarrow \|Aw\|_2 = 0 \Rightarrow Aw = 0 \Rightarrow z = 0$.

Thus, $\mathcal{R}(B_1^H - B_2^H) = 0 \Rightarrow B_1^H = B_2^H \Rightarrow B_1 = B_2$ \square

Of course, $A^H v = 0 \Rightarrow AA^H v = 0$

$\Rightarrow N(AA^H) = N(A^H)$

Thus, $\mathcal{R}(B_1^H - B_2^H) \subset \mathcal{R}(A) \cap N(A^H)$.

Now, if $z \in \mathcal{R}(A)$, $z = Aw$ for some w .

$z \in N(A^H) \Rightarrow A^H z = 0 \Rightarrow A^H A w = 0$

$\Rightarrow w^H A^H A w = 0 \Rightarrow \|Aw\|_2 = 0 \Rightarrow Aw = 0 \Rightarrow z = 0$.

Thus, $\mathcal{R}(B_1^H - B_2^H) = 0 \Rightarrow B_1^H = B_2^H \Rightarrow B_1 = B_2$ \square

Problem: $\min_x \|Ax - b\|_2$.

So, the upshot of that is that the range, so these two are the same and the range space of B_1 Hermitian minus B_2 Hermitian is a subspace, subset of both the range space A and null space of A Hermitian. Now, if you recall that this is actually the null set, then you are done. So basically, that is what the rest of the proof does, is that if there is a Z , which lies in the range space of A , then Z can be written as a linear combination of the columns of A for some W .

And similarly, if Z also belongs to the null space of A Hermitian, then A Hermitian Z equals 0 . And substituting for Z , I have A Hermitian A times W equals 0 , which means that W Hermitian

times A Hermitian AW equals 0 , which means that AW equals 0 , so but Z equals AW , so Z must be equal to 0 .

So, this intersection space contains only the 0 vector. So the range space of B_1 Hermitian minus B_2 Hermitian is 0 , which in turn means that B_1 Hermitian equals B_2 Hermitian, or B_1 equals B_2 . So that concludes the proof. So that is all I have for today. The next class, which is the last class of the course, we will briefly discuss least squares problems.

So, the what we are working up towards is to figure out how to solve Ax equals B . And in particular, in the case where there may not be an exact solution. So those are called least squares problems. In other words, we will ask, what is the, how do we find a solution to the problem minimize with respect to x , Ax minus b l_2 norm and so all these pseudo inverses basically will show up there and help us solve this problem. So that is it for today. And we will meet again on Friday.
