So, we will continue our discussion on bending of circular plates subjected to axis symmetric loading. We have already seen certain points. So, let us just look at them once again. We have got the equation of the deformation in this form,  $\frac{d}{dx} \left[ \frac{1}{x} \frac{d(\phi x)}{dx} \right] = -\frac{V}{D}$ . Wherein this  $\phi$  is nothing but slope and this slope is related to the deflection by this relationship, where the slope is negative. So, that is why it has become in that form.

(Refer Slide Time: 01:38)

So, let us just try to again sketch a portion of the plate. So, this is the plate and this is our  $x$  axis and starting from the centre, we have the  $z$  axis down and another action of the loading like this. We are going to see, that the formation of the plate in this manner and therefore, the slope is now going to be at any point, the slope is like this. That is what is  $\phi$  and, then  $\phi$  is equal to  $-\frac{dw}{dx}$ , because you consider  $w$  to be this distance. That is the distance of the deflection of the centre from the original position.

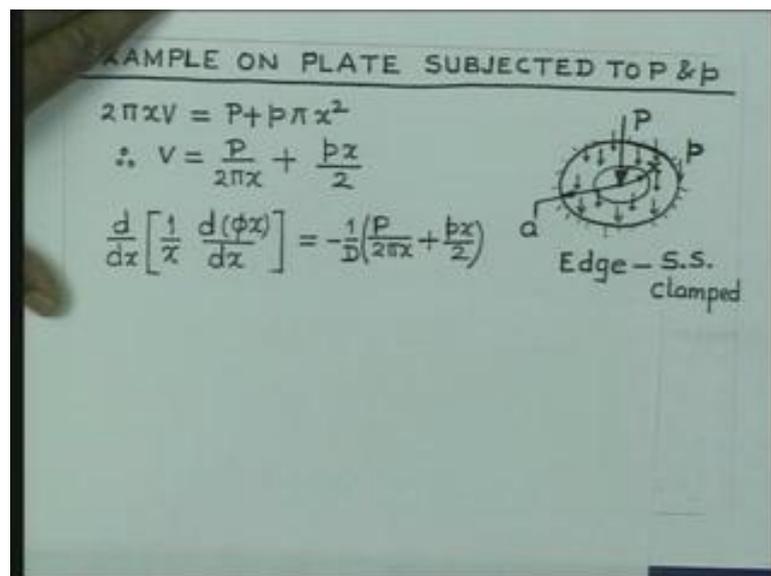

Now, this equation, it is good to work with this form 2. And you have come across, this type of equation in connection with the thick cylinder. We have similar equation and it can be written in a form. So,  $\frac{d}{dx} \left[ \frac{1}{x} \frac{d(\phi x)}{dx} \right] = -\frac{V}{D}$ . And

some of the variables that we introduced, it was  $M_1$ .  $M_1$  was moment per unit length of circumference.

Similarly,  $M_2$  was moment per unit length of radius and  $V$  was shear force per unit length of circumference. Let us now consider some specific examples. Think of a pressure vessel. So, think of this pressure vessel, with the enclosure which is circular and they could be facing through each other by bolts, they could be there could be welding as well. So, this type of, this portion of the plate is subjected to pressure loading like this. We can have some external force also acting. Maybe some load coming up on this plate like this.

So, this is a case of loading wherein, we can now try to look into what sort of deformation. This particular enclosure will undergo and what sort of stresses are going to come up. Now, the end conditions that are going to be persisting here; so if, you would like to consider, that the plate is up to this much, then the end condition at this ends. They can be considered to be clamped or they can be also considered as simply supported. So, we will like to consider both the cases. So, the conditions that can exist at this point and at this point, it can conform to plant condition or simply supported conditions. So, we will now try to consider a general case.

(Refer Slide time: 08:06)

$$\frac{d}{dx} \left[ \frac{1}{x} \frac{d(\phi x)}{dx} \right] = -\frac{1}{D} \left( \frac{P}{2\pi x} + \frac{px}{2} \right) \quad \text{Edge - S.S. Clamped}$$

$$\frac{1}{x} \frac{d(\phi x)}{dx} = -\frac{1}{D} \left\{ \frac{P}{2\pi} \ln x + \frac{px^2}{4} \right\} + c_1 \quad ; \quad c_1 = \text{const.}$$

$$\frac{d(\phi x)}{dx} = -\frac{1}{D} \left\{ \frac{P}{2\pi} x \ln x + \frac{px^3}{4} \right\} + c_1 x$$

$$\therefore \phi x = -\frac{1}{D} \left[ \frac{P}{2\pi} \left\{ \frac{x^2}{2} \ln x - \frac{x^2}{4} \right\} + \frac{px^4}{16} \right] + c_1 \frac{x^2}{2} + c_2$$

So, we have a situation like this, that the plate is let us say, it is supported at the edges and it could be simply supported or clamped. So, it could be clamped as well. So, let us write both the possibilities and we will just go ahead as a general derivation. So, the loading is on the plate, some normal load plus distributed load acting. Now, in order to find out the solution, we must know, what is the shear force per unit length, of circumference at a particular position.

So, let us now consider a position which is at a radial distance of  $x$ . So, therefore, let us consider a circle. So, this is the circle of radius  $x$  and if, we now segregate this portion, we will have forces shear forces acting on its boundary and we can now write; if, we consider that  $V$  is the shear force per unit length on this boundary. Then, in that case we can write now  $2\pi x$  into  $V$  which is going to act in the upward direction and that is to be counter balanced by  $P$  plus  $p$  into  $\pi x^2$ .

So, that is the force balance and this force balance, is going to give us the value of the shear force per unit length that we need. And therefore,  $V$  is equal to  $P$  by  $2\pi x$  plus  $p$  into  $x$  by  $2$ . That's the shear force. We can substitute this value, into the equation of governing equation of deformation of a circular plate  $\frac{d}{dx} \left[ \frac{1}{x} \frac{d(\phi x)}{dx} \right]$  is equal to minus  $\frac{1}{D}$ , for  $V$  we write  $P$  by  $2\pi x$  plus  $px$  by  $2$ .

Now, we this is easily integrable. So, if you do that;  $\frac{1}{x} \frac{d(\phi x)}{dx}$  minus  $\frac{1}{D} \left( \frac{P}{2\pi} \ln x + \frac{px^2}{4} \right)$  plus, there will be 1 arbitrary constant of integration, so that is  $c_1$ , let us say, so this is a constant. Again integrating once more, we get or rather we can

rewrite this expression in this form;  $P$  by  $2\pi$   $x \ln x$  plus  $px$  cube by  $4$  plus  $c_1$  into  $x$ . and if we integrate once more, this gives us  $\phi$   $x$  is equal to minus. This is the case of product of 2 functions. So, you can integrate this first that will give us  $x$  square by  $2 \ln x$ . Then, minus  $x$  square by  $2$ , differentiation of this will give us  $1$  by  $x$ . So, finally, we will have  $x$  by  $2$  and integration of that will give us  $x$  square by  $4$ . So, we are going to get now;  $P$  by  $2\pi$   $x$  square by  $2 \ln x$  minus  $x$  square by  $4$  plus  $px$   $4$  by  $16$  plus  $c_1$   $x$  square by  $2$  plus another constant of integration will come.

(Refer Slide Time: 14:24)

$$\therefore \phi = -\frac{P}{2\pi D} \left[ \frac{x^2}{2} \ln x - \frac{x^2}{4} \right] - \frac{Px^3}{16D} + C_1x + C_2$$

For small deflections:  $\phi = -\frac{dw}{dx}$

$$\therefore \frac{dw}{dx} = \frac{P}{2\pi D} \left[ \frac{x^2}{2} \ln x - \frac{x^2}{4} \right] + \frac{Px^2}{16D} - C_1x - C_2$$

$$\therefore w = \frac{P}{2\pi D} \left[ \frac{x^3}{6} \ln x - \frac{x^3}{12} - \frac{x^3}{6} \right] + \frac{Px^3}{48D} - \frac{C_1x^2}{2} - C_2x + C_3$$

Let us say that is  $c_2$ . So, if we now write finally,  $\phi$ .  $\phi$  is  $P$  by  $2\pi D$ . We have  $x$  by  $2 \ln x$  minus  $x$  by  $4$  minus  $px$  cube by  $16D$  plus  $c_1$  by  $2x$  plus  $c_2$  by  $x$ . So, we have got now the expression for  $\phi$  the slope and now we can certainly go for finding out the deflection since,  $\phi$  is related to the deflection by the formula  $\phi$  is equal to minus  $\Delta w$   $\Delta x$ .

So, we can now consider  $\phi$  as  $\Delta w$  minus  $\Delta w$   $\Delta x$ . And therefore, this is of course, for small deformation because for small deformation, we can write  $\tan \phi$  is equal to  $\phi$  and therefore, small deflections we can write that. And hence, we have  $dw/dx$  is equal to  $P$  by  $2\pi D$   $x$  by  $2 \ln x$  minus  $x$  by  $4$  plus  $px$  cube by  $16D$  minus  $c_1$  by  $2x$  minus  $c_2$  by  $x$ .

Therefore,  $W$  deflection is obtained on integration which is nothing but  $P$  by  $2\pi D$  and integration of this is again a product of 2 functions. So, we will now get  $x$  square by  $4$

$\ln x$  minus  $x$  square by 8. From this we get this 1 and this 1 will give us  $x$  square by 8. This will give us  $p \times 4$  by  $64D$  minus  $c_1$  by  $4 \times x$  square minus  $c_2 \ln x$  plus  $c_3$  wherein again,  $c_3$  is a constant of integration.

(Refer Slide Time: 18:06)

$$\therefore \phi = -\frac{P}{2\pi D} \left\{ \frac{x}{2} \ln x - \frac{x}{4} \right\} - \frac{px^3}{16D} + c_1 x + \frac{c_2}{x}$$

For small deflections:  $\phi = -\frac{dW}{dx}$

$$\therefore \frac{dW}{dx} = \frac{P}{2\pi D} \left\{ \frac{x}{2} \ln x - \frac{x}{4} \right\} + \frac{px^3}{16D} - c_1 x - \frac{c_2}{x}$$

$$\therefore W = \frac{P}{2\pi D} \left\{ \frac{x^2}{4} \ln x - \frac{x^2}{8} - \frac{x^2}{8} \right\} + \frac{px^4}{64D} - \frac{c_1 x^2}{4} - c_2 \ln x + c_3$$

$$= \frac{P}{8\pi D} \left\{ x^2 \ln x - x^2 \right\} + \frac{px^4}{64D} - \frac{c_1 x^2}{4} + c_2 \ln x + c_3$$

Case I: clamped plate;  $P=0, p \neq 0, W=0$  at  $x=a$   
For finite  $W$  everywhere  $c_2=0$ .

So, if we now combine the similar terms, we have  $P$  by  $8 \pi D$   $x$  square  $\ln x$  minus  $x$  square  $px^4$  by  $64D$  minus  $c_1$  by  $4 \times x$  square  $c_2 \ln x$  plus  $c_3$ . This is the complete expression for  $W$  in the case of loading, where we have concentrated load  $P$  and distributed expression  $p$ . Now, let us try to go for specific problem where the plate is clamped and let us also consider that  $P$  is absent. There are no concentrated pores, but there is uniformly distributed pressure over the whole plate.

So, let us try to consider again, the end conditions to be clamped fully clamped plate. So, we have now a case, here it is clamped. Further, we have  $P$  equal to 0 and  $p$  is not equal to 0. You can see that the boundary conditions are obvious, will have deflection equal to 0. If the dimension of the plate is considered to be  $a$ , then at  $x$  equal to  $a$   $w$  equal to 0. Now, the expression for  $w$  that we have here it means: that if you have, if you try to calculate the deflection at the point  $x$  equal to 0 that is, at the centre of the plate, this term will shift to infinity, but we cannot have infinity deflection at any point on the plate. So, for finite deflection everywhere, we must have this constant  $c_2$  equal to 0.

So, for finite  $W$  everywhere,  $c_2$  equal to 0. That is 1 constant is resolved. Now, we will make use of the other boundary conditions. To find out the constants, other boundary

conditions happens to be are as follows. We have the slope at the end of the plate  $x$  equal to  $a$ , that is 0.

(Refer Slide Time: 21:33)

B.c.  $\frac{dW}{dx} = 0$  at  $x=a$ ,  $W=0$  at  $x=a$

$$\frac{dW}{dx} = \frac{px^3}{16D} - \frac{c_1x}{2}$$

$$\left. \frac{dW}{dx} \right|_{x=a} = 0; \quad \frac{pa^3}{16D} - \frac{c_1a}{2} = 0 \quad \therefore c_1 = \frac{pa^2}{8D}$$

$$W = \frac{px^4}{64D} - \frac{pa^2x^2}{32D} + c_3.$$

$$\therefore c_3 = \frac{pa^4}{64D}$$

$$\therefore W = \frac{p}{64D} (a^2 - x^2)^2 \quad W_{\max} = W_{x=0} = \frac{pa^4}{64D}$$

So, we can write now boundary condition, that the slope  $dW/dx$  equal to 0 at  $x$  is equal to  $a$  and at the same time, you do not have any deflection at  $x$  equal to  $a$ . So, therefore, another boundary condition that we have already stated earlier, is that  $W$  equal to 0 at  $x$  equal to  $a$ . So, these 2 conditions are going to suffice, to find out the 2 constants  $c_1$  and  $c_3$ . So, let us now write  $dW/dx$ ,  $dW/dx$  we have only this part of the expression because this  $P$  is 0.

So, therefore, it is going to be  $px^3$  that 4 will cancel and we will have this minus  $c_1x$  by 2. Using the first boundary condition,  $dW/dx$  at  $x$  equal to  $a$  at 0, we have  $pa^3$  by  $16D$  minus  $c_1a$  by 2 equal to 0. So, therefore, constant  $c_1$  is equal to  $pa^2$  by  $8D$ . That's the constant first constant. Now, we can write therefore,  $W$  at  $px$  to the power four by  $64D$  minus  $pa^2x^2$  by  $32D$  plus  $c_3$ . That's the expression for  $W$  and now  $W$  equal to 0 at  $x$  is equal to  $a$ .

So, from that if you put  $x$  is equal to  $a$  then, in that case we are going to get  $c_3$  to be equal to  $pa^4$  by  $64D$  minus  $pa^4$  by  $32D$  and that will give us  $c_3$  equal to  $pa^4$  by  $64D$ . Finally, we have got all the constants and now when you put this in this expression, it forms a quadratic. Therefore, we have  $W$  equal to  $p$  by  $64D$   $a^2$  minus  $x^2$  whole square. So, that is deflection of the plate.

Now, we have to calculate, we are in a position to calculate the deflection very easily. It is obvious; that at  $x$  equal to 0 we are going to have the maximum deflection and therefore,  $W$  maximum, we can write  $W$  maximum and that occurs at  $x$  is equal to 0 and which is nothing but  $\frac{pa^4}{64D}$ . Now, we would like to calculate our other interest, to calculate the maximum stresses. Deflection is resolved. So, therefore, let us now calculate the maximum stresses. For that we must be able to calculate, the maximum bending moment  $M_1$  and  $M_2$  at the critical location.

(Refer Slide Time: 26:06)

The image shows handwritten mathematical derivations for bending moment and stress. The equations are as follows:

$$M_1 = D \left[ \frac{d\phi}{dx} + \nu \frac{\phi}{x} \right]$$

$$= D \left[ \frac{p}{16D} (a^2 - 3x^2) + \nu \frac{p}{16D} (a^2 - x^2) \right]$$

$$M_2 = \frac{p}{16} [a^2(1+\nu) - x^2(1+3\nu)]$$

$$M_1|_{x=a} = \frac{p}{16} [a^2 - 3a^2 + \nu(0)] = -\frac{pa^2}{8}$$

$$M_2|_{x=a} = -\frac{\nu pa^2}{8} \quad \sigma_1|_{max} = \frac{6M}{h^2} = +\frac{3\nu pa^2}{4h^2} \text{ (top)}$$

$$\sigma_2|_{max} = \frac{3\nu pa^2}{4h^2} \text{ (top)}$$

So, for doing that we will have to find out the radius of curvature and therefore, now we will write  $\phi$  as  $-\frac{dW}{dx}$  and that is equal to  $-\frac{p}{64D} a^2 x^2$ . So, we are just making use of this relationship and we have this multiplied by  $2x$  and that is nothing but  $\frac{p}{16D} x^2(a^2 - 3x^2)$ . So, that is the expression for the slope  $\phi$  and we can now write,  $\frac{d\phi}{dx}$  is equal to  $\frac{p}{16D} (2ax - 6x^3)$ . So, you can write this thing as  $\frac{p}{16D} (2ax - 6x^3)$ . So, that gives us  $\frac{d\phi}{dx}$ .

We have the bending moment  $M_1$  which is in the  $xz$  plane  $D \left[ \frac{d\phi}{dx} + \nu \frac{\phi}{x} \right]$ . So, if we substitute the values  $\frac{p}{16D} (2ax - 6x^3) + \nu \frac{p}{16D} (a^2 - x^2)$ . So, therefore, it is  $\frac{p}{16D} (2ax - 6x^3 + \nu a^2 - \nu x^2)$ . So,  $D$  get cancelled. This  $D$  will cancel everywhere. So, it will become independent of  $D$ . So, we will have  $M_1$  equal to  $\frac{p}{16} (2ax - 6x^3 + \nu a^2 - \nu x^2)$ .

Similarly,  $M_2$  is going to be given by  $D \int \phi dx$ . So, we can now write  $M_2$  which will be like this;  $p \int_0^a (1 + \nu x^2) dx$ . So,  $M_2$  at  $x = a$ . We see that the, at  $x = a$  we are going to have the maximum bending moment. We will try to calculate the bending moment at  $x = a$ . So,  $M_2$  at  $x = a$  is equal to  $p \int_0^a (1 + \nu x^2) dx = p [x + \frac{\nu x^3}{3}]_0^a = p [a + \frac{\nu a^3}{3}]$  and therefore, this is nothing but  $pa^2$  by 8.

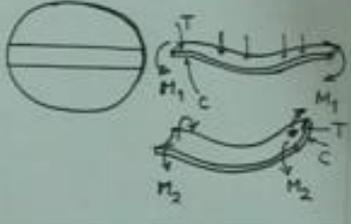

Similarly,  $M_1$  at  $x = a$  is equal to, here  $x = a$ . So, we will have this term canceling, here it is  $\nu$  and here it is  $3\nu$ . So, we will be left with 2 and 2 will cancel with 16. So, therefore, we will have  $\nu pa^2$  by 8. So, these are the bending moments at the end of the plate. Now, let us try to see how the stresses are going to come up. Because of this bending moment, we will have a stress which is given by extreme fiber stress, which is maximum which is nothing but can be calculated from the formula  $\frac{6M}{h^2}$ , because here  $p = 1$ . So,  $\frac{6M}{h^2}$  is unity.

So, we can write now  $\frac{6M}{h^2}$  and since, this is  $pa^2$  by 8. So, we can now have this substituted here and this will give us  $3 \times 4 \frac{pa^2}{h^2}$ . So, this is the stress. It is if, we consider the stress at the top fiber that is the value top. Likewise if, we calculate the maximum stress due to  $M_2$ ,  $\sigma_2$  maximum is equal to it is simply  $\nu pa^2$  by  $h^2$ . So, here in the value is this and therefore, we will have  $\nu pa^2$  6 times this divided by  $h^2$ . So, that gives us we will again have of course, 3 by 4 factor will be there and this is the stress at the top fiber. It is very important to see, how this both the stresses are going to be positive at the top fiber.

(Refer Slide Time: 33:02)

$$M_1|_{x=a} = \frac{b}{16} [a^2 - 3a^2 + \nu(0)] = -\frac{pa^2}{8}$$

$$M_2|_{x=a} = -\frac{\nu pa^2}{8} \quad \sigma_1|_{\max} = \frac{6M}{h^2} = +\frac{3}{4} p \frac{a^2}{h^2} \text{ (top)}$$

$$\sigma_2|_{\max} = \frac{3}{2} \nu p \frac{a^2}{h^2} \text{ (top)}$$

So, let us look into, look at the plate which is circular. Let us now consider only a portion of it at the centre and I have drawn it here. So, this is the portion which is subjected to bending. So, because of the pressure acting all over, it is going to bend like this and you see here, that the curvature that is going to be here is negative, whereas the curvature here that is going to come up is positive curvature and this is possible as the bending moment is acting like this. Already we have seen that  $M_1$  and  $M_2$  both are negative bending moment.

So, this  $M_1$  at the end is minus  $pa^2$  by 8. So, its negative bending moment and it acts like this. Now, under the action of this bending moment, we will have tensile stresses developed at the top, compressive stresses at the bottom. So, therefore, you here expect tensile stresses and at the bottom, we are going to get compressive stresses. And anticlastic curvature will develop such that, since compression is there, there will be extension here and contraction at the top. So, the anticlastic curvature will develop which is going to look like this. The plate is going to really, it is going to deform at the edges like this.

Since, it is clamped, this sort of curvature cannot come up and therefore, we will find that, there will be bending moment developed like this which is  $M_2$ . So, this bending moment will try to, this bending moment will try to develop like this to undo that curvature. So, therefore, this bending moment is negative, because you have considered

the other direction to be positive. So, therefore, this is also negative bending moment. That's what have come and under the action of this type of bending moment we can; obviously, see that at this point, at the bottom we are going to see compression. And at the top we are going to see tension.

So, therefore, we will have tension at the top compression at the bottom. So, in both the cases, you see that we are going to have tension at the top and compression at the bottom. And these stresses are tension at the top compression at the bottom that is why, these stresses are both positive.

(Refer Slide Time: 36:29)

Case II: Simply Supported Plate,  $P=0, p \neq 0$ .

B.C.  $\phi=0$  at  $x=0$ ;  $w=0$  at  $x=a$   
 $M_1=0$  at  $x=a$

$$w = \frac{px^4}{64D} - \frac{C_1}{4}x^2 - C_2 \ln x + C_3;$$

$$\phi = -\frac{dw}{dx} = -\left[\frac{px^3}{16D} - \frac{C_1}{2}x - \frac{C_2}{x}\right]$$

$$\phi=0 \text{ at } x=0 \rightarrow C_2=0$$

Now, we will try to consider the case of a simply supported plate. Let us see the other extreme, when a plate is simply supported what happens. Again we are trying to look for the case, when  $P$  is 0 and  $p$  is not equal to 0 and in the case of the simply supported plate, we would have conditions like; at  $x$  is equal to  $a$ , at the outer edge of the plate we will have deflection equal to 0 and bending moment equal to 0. A bending moment in the circumferential direction will be 0.

So,  $M_1$  equal to 0 and we are going to get the slope at the centre of the plate to be 0. So, we can now write the boundary conditions  $\phi$  equal to 0 at  $x$  equal to 0. Then,  $w$  equal to 0 at  $x$  is equal to  $a$  and bending moment equal to  $a$ . Bending moment of course,  $M_1$  equal to 0 at  $x$  is equal to  $a$ . And our case is  $P$  is 0 and  $p$  is not equal to 0. We proceed as

before. In this case we start with this expression of  $w$   $w$  is equal to  $\frac{px^4}{64D}$  minus  $c_1$  by  $4x$  square minus  $c_2 \ln x$  plus  $c_3$ .

Now, we can write  $\phi$  minus  $\frac{dw}{dx}$  is equal to minus  $\frac{px^3}{16D}$  minus  $c_1$  by  $2x$  minus  $c_2$  by  $x$ . The slope as we have slope equal to 0 at  $x$  equal to 0. So,  $\phi$  equal to 0 at  $x$  is equal to 0, and that means this term is going to shift to infinity. Therefore, this constant must be equal to 0 to have finite value of the slope.

(Refer Slide Time: 39:38)

Handwritten mathematical derivation on a whiteboard:

$$\begin{aligned}
 & \text{B.C. } \phi = 0 \text{ at } x=0, \quad w = 0 \text{ at } x=a \\
 & M_1 = 0 \text{ at } x=a \\
 & w = \frac{px^4}{64D} - \frac{c_1}{4}x^2 - c_2 \ln x + c_3; \\
 & \phi = -\frac{dw}{dx} = -\left[\frac{px^3}{16D} - \frac{c_1}{2}x - \frac{c_2}{x}\right] \\
 & \phi = 0 \text{ at } x=0 \rightarrow c_2 = 0 \\
 & w = 0 \text{ at } x=a \rightarrow \frac{pa^4}{64D} - \frac{c_1}{4}a^2 + c_3 = 0 \dots (1)
 \end{aligned}$$

Finally therefore, we can now make use of the condition that  $w$  equal to 0 at  $x$  equal to  $a$ . So, we have now we will just substitute  $w$  equal to 0 at  $x$  is equal to  $a$ , noting that we have already got  $c_2$ . So, therefore, this is going to be  $\frac{pa^4}{64D}$  minus  $c_1$  by  $4a^2$  square plus  $c_3$  equal to 0. So, this is equation number 1 we have got 2 constants involved.

(Refer Slide Time: 40:31)

$$\begin{aligned}
 M_1 &= D \left[ \frac{d\phi}{dx} + \nu \frac{\phi}{x} \right]; \frac{d\phi}{dx} = - \left[ \frac{3px^2}{16D} - \frac{c_1}{2} \right] \\
 &= D \left[ -\frac{3px^2}{16D} + \frac{c_1}{2} - \nu \frac{px^2}{16D} + \nu \frac{c_1}{2} \right] \\
 &= -\frac{(3+\nu)}{16} px^2 + \frac{(1+\nu)}{2} c_1 D
 \end{aligned}$$

$$\begin{aligned}
 \phi &= -\frac{dw}{dx} = - \left[ \frac{px^3}{16D} - \frac{c_1}{2}x - \frac{c_3}{x} \right] \\
 \phi &= 0 \text{ at } x=0 \rightarrow c_3 = 0 \\
 w &= 0 \text{ at } x=a \rightarrow \frac{pa^4}{64D} - \frac{c_1}{4}a^2 + c_3 = 0 \dots (1) \\
 &-\frac{3+\nu}{16} pa^2 + \frac{(1+\nu)}{2} c_1 D = 0 \dots (2) \\
 \therefore c_1 &= \frac{3+\nu}{8(1+\nu)} pa^2 \\
 (1) \rightarrow c_3 &= -\frac{pa^4}{64D} + \frac{(3+\nu)}{32(1+\nu)} pa^4 = \frac{2(3+\nu) - (1+\nu)}{64(1+\nu)} pa^4 \\
 &= \frac{pa^4 (5+\nu)}{64D (1+\nu)}
 \end{aligned}$$

Now, we can make use of the other boundary condition provided we have the expression for bending moment  $M_1$ . So, if we consider bending moment  $M_1$  which is,  $D$  into  $d\phi/dx$  plus  $\nu$  times  $\phi$  by  $x$  and therefore,  $d\phi/dx$  is equal to minus  $3px^2$  by  $16D$  minus  $c_1$  by  $2$ . And hence we can now write  $D.M_1$  as  $D$  into  $3px^2$  by  $16D$  plus  $c_1$  by  $2$  minus  $\nu$  times  $\phi$  which is  $\phi$  by  $x$  of course, we have  $px^2$  by  $16D$  nu  $c_1$  by  $2$ . That's the value for  $M_1$  and since  $M_1$  is equal to  $0$  at  $x$  is equal to  $a$ . So, this of course, we can write in a neater form, because this  $D$  is going to cancel for this 2 terms.

Therefore, we can write now  $3$  plus  $\nu$  by  $16$   $p$   $x^2$  plus  $1$  plus  $\nu$  by  $2$   $c_1$  into  $D$  and since,  $M_1$  equal to  $0$  at  $x$  is equal to  $a$ , we now get equation involving  $c_1$  like this

and therefore, we get  $c_1$  equal to  $3 + \nu$  by  $8$  into  $1 + \nu$  into  $D p a^2$ . And if we get back to earlier equation 1, which is here; from that equation, substituting the value of  $c_1$  we can now obtain  $c_3$ . So, therefore,  $c_3$  is equal to  $\frac{-p a^4}{64D}$  plus  $a^2$  by  $4 c_1$ . So, therefore, it will be  $3 + \nu$  by  $32$  into  $1 + \nu$  into  $D p a^4$  and that gives us  $2$  into  $3 + \nu$  minus  $1 + \nu$  by  $64$  into  $1 + \nu$   $D p a^4$  to the power 4, which simplifies to  $\frac{p a^4}{64D} \frac{3 + \nu}{1 + \nu}$ . So, we can now substitute the value of  $c_1$  and  $c_2$  and recover the expression for deflection and slope.

The image shows handwritten mathematical derivations on a whiteboard. The equations are as follows:

$$w = \frac{p x^4}{64D} - \frac{(3+\nu)}{32(1+\nu)D} p a^2 x^2 + \frac{(5+\nu)}{64D(1+\nu)} p a^4$$

$$w|_{\max} = + \frac{(5+\nu)}{64D(1+\nu)} p a^4; \quad \phi = -\frac{p x^3}{16D} + \frac{(3+\nu)}{16(1+\nu)D} p a^2$$

$$M_1 = -\frac{3+\nu}{16} p x^2 + \frac{3+\nu}{16} p a^2 = +\frac{3+\nu}{16} p (a^2 - x^2)$$

$$M_1|_{\max} = \frac{3+\nu}{16} p a^2$$

$$M_2 = D \left[ \frac{d}{dx} + \nu \frac{d\phi}{dx} \right]$$

So, let us now again put the values back and get the expression for  $w$ .  $w$  is equal to  $\frac{p x^4}{64D}$  minus  $\frac{3 + \nu}{32}$  into  $1 + \nu$   $D p a^2 x^2$  plus  $\frac{5 + \nu}{64D}$  into  $1 + \nu$   $p$  raise to the power 4. And you can see that, the maximum deflection of the plate is going to occur at  $x$  equal to 0 and the value of the maximum deflection is given by this expression.

So, in the case, the maximum deflection is going to occur again at the centre and this maximum deflection is equal to  $\frac{5 + \nu}{64D}$   $1 + \nu$   $p a^4$  and the value of  $\phi$  is now  $\frac{p x^3}{16D}$  plus  $\frac{3 + \nu}{16}$   $1 + \nu$  into  $D p a^2$  into  $x$ . That's the value for  $\phi$  and if, we calculate  $M_1$  which is,  $M_1$  is nothing but  $D$  into  $d\phi/dx$  plus  $\nu \phi$  by  $x$ . So, we have everything.

So, if we substitute, the expression for  $M_1$  turns out to be  $M_1$  is equal to  $\frac{3 + \nu}{16} p x^2$  plus  $\frac{3 + \nu}{16} p a^2$ . So, this as a simplified form  $\frac{3 + \nu}{16} p (a^2 - x^2)$ .

sixteen  $pa^2$  minus  $x^2$  and hence, value of maximum bending moment is equal to  $\frac{3}{16}(3+\nu)pa^2$ .

(Refer Slide Time: 48:31)

$$M_2 = D \left[ -\frac{px^2}{16D} + \frac{(3+\nu)}{16(1+\nu)D} pa^2 + \nu \left\{ -\frac{3px^2}{16D} + \frac{(3+\nu)}{16(1+\nu)D} pa^2 \right\} \right]$$

$$= \frac{p}{16} \left[ a^2(3+\nu) - x^2(1+3\nu) \right]$$

$$M_2|_{\max} = \frac{pa^2}{16} (3+\nu)$$

$$\therefore \sigma_1|_{\max} = \frac{6(3+\nu)pa^2}{16h^2} = \frac{3}{8}(3+\nu) \frac{pa^2}{h^2}$$

$$= \sigma_2|_{\max}$$

Similarly, if we calculate  $M_2$  which is nothing but  $D \int \phi \frac{d^2\phi}{dx^2}$ . So,  $D \int \phi \frac{d^2\phi}{dx^2}$ , one should do the substitution in this, we get  $M_2$  minus  $px^2/16D$  plus  $\frac{3+\nu}{16(1+\nu)D} pa^2$  plus  $\nu$  times  $d\phi/dx$   $\frac{3+\nu}{16(1+\nu)D} pa^2$ . So, it is  $\frac{3+\nu}{16(1+\nu)D} pa^2$ . And this gets simplified; a square  $3+\nu$  minus  $x^2(1+3\nu)$  this expression. And hence,  $M_2$  maximum is at  $x$  equal to 0 which is  $\frac{3+\nu}{16} pa^2$ . So, finally, we have been able to get the maximum of both the moments

Handwritten mathematical derivations on a whiteboard:

$$w = \frac{px^4}{64D} - \frac{(3+\nu)}{32(1+\nu)D} pa^2x^2 + \frac{(5+\nu)}{64D(1+\nu)} pa^4$$
$$w|_{\max} = + \frac{(5+\nu)}{64D(1+\nu)} pa^4; \quad \phi = -\frac{bx^3}{16D} + \frac{(3+\nu)}{16(1+\nu)D} pa^2x$$
$$M_1 = -\frac{3+\nu}{16} px^2 + \frac{3+\nu}{16} pa^2 = +\frac{3+\nu}{16} p(a^2-x^2)$$
$$M_1|_{\max} = \frac{3+\nu}{16} pa^2$$
$$M_2 = D \left[ \frac{d}{dx} + \nu \frac{d\phi}{dx} \right]$$

M 1 maximum we have got already 3 plus nu by 16 pa square. M 2 maximum is also of the same magnitude and hence now, we have at x equal to 0 sigma 1 max is equal to, it is nothing but 6 times the moment divided by h square and therefore, that will become, 3 plus nu pa square by sixteen h square and this is 3 by 8 3 plus nu pa square by h square. And in fact, the stress in the circumferential direction is also the same. So, therefore, sigma 2 maximum is also of the same magnitude. You can think physically also to establish that sigma 1 maximum is equal to sigma 2 maximum.

Handwritten mathematical derivations and a diagram on a whiteboard:

$$\sigma_2|_{\max} = \frac{pa}{16} (3+\nu)$$
$$\therefore \sigma_1|_{\max} = \frac{6(3+\nu) pa^2}{16 h^2} = \frac{3}{8} (3+\nu) \frac{pa^2}{h^2}$$
$$= \sigma_2|_{\max}$$

Diagram: A circle representing a cross-section with a vertical diameter labeled  $\sigma_2 = \sigma_1$  and a horizontal diameter labeled  $\sigma_1$ .

We can consider the plate. This is the centre of the plate and we have seen that, at the centre  $\sigma_1$  max is equal to  $\frac{3}{8} \frac{p a^2}{h^3} (1 + \nu)$ . If you consider that, this is the direction of  $\sigma_1$  which is a radial direction. Now, the perpendicular direction is this  $\sigma_2$ . This is also a radial direction. Since, this is axis symmetric, the stress in this direction which we indicate to be  $\sigma_2$ , it has got to be equal to  $\sigma_1$  and hence, at the centre the stress in this direction is maximum. So, also it is going to be maximum in this direction and hence  $\sigma_1$  maximum is equal to  $\sigma_2$  maximum.

The picture is not different in the case of clamp plate as well. Only the boundary condition will change, but at the centre we will have again  $\sigma_1$  maximum is equal to  $\sigma_2$  maximum. For the case of simply supported plate and also for the case of clamp plate, we can find out the stress variation along the radius and they can be compared. We will compare this in our next lecture.
