Lecture – 8

(Refer Slide Time: 01:11)

We would like to consider in this lecture, relative displacement tensor, rotation tensor and strain tensor. We have already seen earlier, how the strain tensor is defined, we would like to look into little more into the definition. And so that this strain tensor is related to relative displacement tensor and rotation tensor, when you consider any component loaded, it will undergo displacements. And those displacements can include the rigid body displacements, it can also include the deformation. So, let us try to look into specifically into the case, we have consider three dimensions.

And our axis are oriented as usual consider a body, which is loaded I am not showing the load here, that this is the body which is subjected to loading. And under the action of loading it can move it can rotate. So therefore, it can have deformation also it can, it is moving in space and it has both rotation and deformation. So, if you confine or attention onto two points, although we have showing it to be this two points to be widely apart.

But in fact, are interest to consider this two points, which are closed by... So, these are the two points. Now, are it moves in the position that we have shown here, it might take

up orientation, which is given by P dash and Q dash. So, the point has move within space like this. Let us consider that the distance between P Q can be indicated as a vector quantity.

And let us say, that this is the vector A and this vector has components A x in the x direction A y in the y direction and A z in the z direction. So, we can write A to B i A x plus j A y plus k A z. Now, the displacement of any point on this body will make use of this function as usual u for the x direction, v for the y direction and w for the z direction.

This u; obviously, it is going to be a function of the coordinate of the point. So, they are function of... So, this u i if you try to write in the form of the tensor, it is going to be function of x, y, z, i it takes some value 1, 2, 3. And in specific in to the specific i equal to 1 indicates u and i equal to 2 indicates v and i equal to 3 indicates w. Now, we would like to consider that the displacement of the point P.

(Refer Slide Time: 05:29)

Handwritten mathematical derivation on a whiteboard:

$$\left. \begin{aligned} u &= u_0 \\ v &= v_0 \\ w &= w_0 \end{aligned} \right\} P \quad \begin{aligned} u &= u_0 + \frac{\partial u}{\partial x} A_x + \frac{\partial u}{\partial y} A_y + \frac{\partial u}{\partial z} A_z \\ &+ \frac{1}{2} \left[\left(\frac{\partial u}{\partial x} \right)^2 A_x + \left(\frac{\partial u}{\partial y} \right)^2 A_y \right. \\ &\quad \left. + \left(\frac{\partial u}{\partial z} \right)^2 A_z \right] + \dots \\ v &= v_0 + \frac{\partial v}{\partial x} A_x + \frac{\partial v}{\partial y} A_y + \frac{\partial v}{\partial z} A_z + \dots \\ w &= w_0 + \frac{\partial w}{\partial x} A_x + \frac{\partial w}{\partial y} A_y + \frac{\partial w}{\partial z} A_z + \dots \end{aligned}$$

Neglecting second order term

$$\begin{Bmatrix} u - u_0 \\ v - v_0 \\ w - w_0 \end{Bmatrix} = \begin{bmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} & \frac{\partial u}{\partial z} \\ \frac{\partial v}{\partial x} & \dots & \frac{\partial v}{\partial z} \\ \frac{\partial w}{\partial x} & \dots & \frac{\partial w}{\partial z} \end{bmatrix} \begin{Bmatrix} A_x \\ A_y \\ A_z \end{Bmatrix}$$

Let us say that displacement of the point P is u 0 and v is v 0, w is w 0. Now, you can write the displacement of the point Q, which is at a small distance apart from P. So, this are the displacements of the point P. Now, if you want to write the displacement of the point Q you can write like this u equal to u 0 plus you can write the ((Refer Time: 06:29)) expansion for the functions u i.

So therefore, we will have $\Delta u \Delta x A_x$ plus $\Delta u \Delta y A_y$ plus $\Delta u \Delta z A_z$, that will be first order term. Then, we are also going to get second order terms which are nothing but $\Delta u \Delta x^2$ into A_x plus $\Delta u \Delta y^2$ into A_y plus $\Delta u \Delta z^2$ into A_z and you can have higher order terms.

So, we can write similar expression for the other displacement. So, we can also be retained. So, v is nothing but v_0 plus $\Delta v \Delta x A_x$ plus $\Delta v \Delta y A_y$ plus $\Delta v \Delta z A_z$ plus we have the second order terms and third order terms And so on. Similarly, w can be written as w_0 plus $\Delta w \Delta x A_x$ plus $\Delta w \Delta y A_y$ plus $\Delta w \Delta z A_z$ plus the higher order terms.

Now, if we neglect the second order terms. We can write the following, you can write $u - u_0$ $v - v_0$ $w - w_0$ this is nothing but a compact form. Then, we will have $\Delta v \Delta x \Delta v \Delta y$ then $\Delta w \Delta z$. And the last row will have the derivatives of $\Delta w \Delta x \Delta w \Delta y \Delta w \Delta z$. So therefore, this multiplied by components of $A_x A_y A_z$, this can be written in an compact form using tensor rotation.

(Refer Slide Time: 11:20)

The image shows a handwritten derivation on a whiteboard. At the top, there is a vector equation: $(u - u_0) \begin{bmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} & \frac{\partial u}{\partial z} \end{bmatrix} (A_x)$. Below this, the displacement component $u_i - u_{i0}$ is expressed as $u_{i,j} A_j$, labeled as equation (1). The indices $i, j = 1, 2, 3$ are specified. Then, the tensor $u_{i,j}$ is defined as the partial derivative $\frac{\partial u_i}{\partial x_j}$, which is represented as a 3x3 matrix of partial derivatives: $\begin{bmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} & \frac{\partial u}{\partial z} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} & \frac{\partial v}{\partial z} \\ \frac{\partial w}{\partial x} & \frac{\partial w}{\partial y} & \frac{\partial w}{\partial z} \end{bmatrix}$. A note below the matrix states: "Relative displacement tensor."

We can make use of that $u_i - u_{i0}$ is equal to $u_{i,j} A_j$. So, this relationship, let us indicate by 1. Here, in this gives the this $u_i - u_{i0}$ here in of course, you have assume that i is taking up value 1, 2, 3 and j is taking up value also 1, 2, 3. And this $u_{i,j}$, this indicates really all the derivatives.

So, therefore, u_{ij} is nothing but $\delta u_i \delta x_j$. And here, we have all the 9 derivatives. And this is nothing but the this expanded form which we have given earlier. So, this consist of all the 9 derivatives. And this is known as relative displacement tensor. This, since the displacements between the two points P and Q are changing by ((Refer Time: 13:52)) this match, this indicates really the change in the length. So, p moves in the x direction by u_0 and Q moves by the distance u . So, therefore, in the x direction, there is a change in the length u minus u_0 .

(Refer Slide Time: 14:24)

Handwritten mathematical derivation on a whiteboard:

$$\delta A_i = u_{i,j} A_j \dots \dots (2)$$

↳ Affine transformation

Initial A_i
 Final $A_i + \delta A_i$

$$(A_x^2 + A_y^2 + A_z^2) = (A_x + \delta A_x)^2 + (A_y + \delta A_y)^2 + (A_z + \delta A_z)^2$$

OR, $2A_x \delta A_x + 2A_y \delta A_y + 2A_z \delta A_z = 0$
 neglecting δA_i^2 terms

$$A_x \left(\frac{\partial u}{\partial x} A_x + \frac{\partial u}{\partial y} A_y + \frac{\partial u}{\partial z} A_z \right)$$

So, the change in the length of the distance P Q if we indicate by δA_i ((Refer Time: 15:40)). Then, we will have the components of the change are δA_x , δA_y and δA_z . Then, it is very easy to realize, that this δA_i is nothing but u_i minus u_{i0} . So, we can now write δA_i is equal to $u_{i,j}$ multiplied by A_j . This is known as affine transformation. Now, the changes in the length in the x, y and z direction between the two points is given by this affine transformation. So, the initial component of the distance are A_i and the final components of the distance are $A_i + \delta A_i$.

Now, if you consider that the body displaced in such a way, that there was no deformation. That means, distance between P and Q remained unchanged, then we are going to get that the initial square of the length between the two points are given by $A_x^2 + A_y^2 + A_z^2$ that will be initial distance square. And that must

be equal to $A_x \delta A_x + A_y \delta A_y + A_z \delta A_z$ square.

Now, this will give us twice $A_x \delta A_x$ plus twice $A_y \delta A_y$ plus twice $A_z \delta A_z$ equal to 0 neglecting δA_i square terms. Now, we have the expression for δA_x , δA_y and δA_z . So, if we now consider and if we write then and it is going to give us $A_x \delta u + A_x \delta v + A_x \delta w$ plus $A_y \delta u + A_y \delta v + A_y \delta w$ plus $A_z \delta u + A_z \delta v + A_z \delta w$ ((Refer Time: 18:57)). Plus $A_x \delta v + A_x \delta w$ plus $A_y \delta v + A_y \delta w$ plus $A_z \delta v + A_z \delta w$.

(Refer Slide Time: 19:27)

Handwritten mathematical derivation on a whiteboard:

$$+ A_z \left(\frac{\partial u}{\partial x} A_z + \frac{\partial v}{\partial y} A_y + \frac{\partial w}{\partial z} A_z \right) = 0$$

$$A_x^2 \frac{\partial u}{\partial x} + A_y^2 \frac{\partial v}{\partial y} + A_z^2 \frac{\partial w}{\partial z}$$

$$+ A_x A_y \left(\frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right) + A_y A_z \left(\frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \right)$$

$$+ A_z A_x \left(\frac{\partial w}{\partial x} + \frac{\partial u}{\partial z} \right) = 0 \quad \dots (3)$$

Rigid body displacement condition

$$\frac{\partial u}{\partial x} = 0 \quad \frac{\partial v}{\partial y} = 0 \quad \frac{\partial w}{\partial z} = 0$$

$$\left(\frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right) = 0 \quad \left(\frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \right) = 0 \quad \left(\frac{\partial w}{\partial x} + \frac{\partial u}{\partial z} \right) = 0$$

..... (4)

Plus we are going to get the third component plus $A_z \delta u + A_z \delta v + A_z \delta w$ plus $A_x \delta v + A_x \delta w$ plus $A_y \delta v + A_y \delta w$ plus $A_z \delta v + A_z \delta w$ equal to 0. So, this if we now rearrange it is going to be $A_x^2 \delta u + A_y^2 \delta v + A_z^2 \delta w$ plus $A_x \delta v + A_x \delta w$ plus $A_y \delta v + A_y \delta w$ plus $A_z \delta v + A_z \delta w$.

Plus $A_z \delta u + A_x \delta v + A_x \delta w$ plus $A_y \delta v + A_y \delta w$ plus $A_z \delta v + A_z \delta w$ equal to 0. Now, this relationship if we call it 3, if we have A_x, A_y, A_z they are always positive and at the same time call this quantities are positive. So, therefore, if the left hand side is to be 0, this demand that the coefficient of all this terms have got to be 0. So therefore rigid body displacement condition.

So, the body is going to move like a rigid body without deformation is going to be coefficient of all these terms are 0. So therefore, it means that $\Delta u \Delta x = 0$, $\Delta v \Delta y = 0$, $\Delta w \Delta z = 0$. And then, we have $\Delta u \Delta y + \Delta v \Delta x = 0$, $\Delta v \Delta z + \Delta w \Delta y = 0$ and $\Delta w \Delta x + \Delta u \Delta z = 0$. So, these six conditions are the conditions for the rigid body displacement.

(Refer Slide Time: 23:47)

The image shows a handwritten derivation of the displacement tensor $u_{i,j}$. It is expressed as the sum of a strain tensor ϵ_{ij} and a rotation tensor ω_{ij} .

$$u_{i,j} = \begin{bmatrix} \frac{\partial u}{\partial x} & \frac{1}{2}(\frac{\partial v}{\partial y} + \frac{\partial u}{\partial x}) & \frac{1}{2}(\frac{\partial w}{\partial z} + \frac{\partial u}{\partial x}) \\ \frac{1}{2}(\frac{\partial v}{\partial x} + \frac{\partial u}{\partial y}) & \frac{\partial v}{\partial y} & \frac{1}{2}(\frac{\partial w}{\partial z} + \frac{\partial v}{\partial y}) \\ \frac{1}{2}(\frac{\partial w}{\partial x} + \frac{\partial u}{\partial z}) & \frac{1}{2}(\frac{\partial w}{\partial y} + \frac{\partial v}{\partial z}) & \frac{\partial w}{\partial z} \end{bmatrix} \rightarrow \epsilon_{ij}$$

$$+ \begin{bmatrix} 0 & \frac{1}{2}(\frac{\partial v}{\partial y} - \frac{\partial u}{\partial x}) & \frac{1}{2}(\frac{\partial w}{\partial z} - \frac{\partial u}{\partial x}) \\ \frac{1}{2}(\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}) & 0 & \frac{1}{2}(\frac{\partial w}{\partial z} - \frac{\partial v}{\partial y}) \\ \frac{1}{2}(\frac{\partial w}{\partial x} - \frac{\partial u}{\partial z}) & \frac{1}{2}(\frac{\partial w}{\partial y} - \frac{\partial v}{\partial z}) & 0 \end{bmatrix} \rightarrow \omega_{ij}$$

Below the matrices, it is noted that $\epsilon_{ij} \rightarrow$ Strain tensor and $\omega_{ij} \rightarrow$ Rotation. The final result is summarized as $u_{i,j} = \epsilon_{ij} + \omega_{ij}$.

Now, the relative displacement tensor we can rearrange it, relative displacement tensor can be now rearrange like this, that u_{ij} is equal to $\Delta u \Delta x + \frac{1}{2}(\Delta u \Delta y + \Delta v \Delta x) + \frac{1}{2}(\Delta u \Delta z + \Delta w \Delta x)$. Then, we have $\frac{1}{2}(\Delta v \Delta x + \Delta u \Delta y) + \frac{1}{2}(\Delta v \Delta z + \Delta w \Delta y)$ this is plus this is $\Delta v \Delta z + \Delta w \Delta y$.

Then, we have $\frac{1}{2}(\Delta w \Delta x + \Delta u \Delta z) + \frac{1}{2}(\Delta w \Delta y + \Delta v \Delta z) + \Delta w \Delta z$ and $\Delta w \Delta z$. So, this is the first part and then, we try to write plus 0, this is $\frac{1}{2}(\Delta u \Delta y - \Delta v \Delta x) + \frac{1}{2}(\Delta u \Delta z - \Delta w \Delta x)$. Then, this is $\frac{1}{2}(\Delta v \Delta x - \Delta u \Delta y) + 0 + \frac{1}{2}(\Delta v \Delta z - \Delta w \Delta y)$.

Then this one $\frac{1}{2}(\Delta w \Delta x - \Delta u \Delta z) + \frac{1}{2}(\Delta w \Delta y - \Delta v \Delta z) + \Delta w \Delta z = 0$. So, if we just write this we get back, you can see that here we have added something we subtracted something. And then, these two terms give me back the original

expression for u_{ij} . And you can see that, this is nothing but the strain tensor, this is the ϵ_{ij} this is γ_{xy} , this is γ_{xz} , this is γ_{yz} this is γ_{zx} , γ_{zy} and ϵ_{zz} and this is the strain tensor.

So therefore, this is the strain tensor ϵ_{ij} and this one is nothing but it is giving us the condition, that it is rotation this is the rotational tensor. So therefore, this gives the rotation tensor ω_{ij} . So therefore, ϵ_{ij} is the strain tensor and ω_{ij} is the rotation tensors. So, you consider the relative displacement tensor is nothing but sum of the u_{ij} relative displacement tensor is nothing but sum of the strain tensor and the rotation tensor here ϵ_{ij} we will indicate this thing, this will indicate this thing as ω_{ij} . So therefore, this is ω_{ij} . So, relative displacement tensor is sum of the strain tensor and the rotation tensor.

(Refer Slide Time: 29:57)

Handwritten mathematical derivation on a slide:

$$u_{i,j} \rightarrow \text{Rotation } \dots$$

$$u_{i,j} = \frac{1}{2} [u_{i,j} + u_{j,i}] + \frac{1}{2} [u_{i,j} - u_{j,i}]$$

$\underbrace{\hspace{10em}}_{\epsilon_{ij}} \qquad \underbrace{\hspace{10em}}_{\omega_{ij}}$

For pure deformation $\omega_{ij} = 0$

$$u_{i,j} = u_{j,i}$$

DETERMINATION OF PRINCIPAL STRAINS

$$\delta A_i = \frac{1}{2} (u_{i,j} + u_{j,i}) A_j = \epsilon_{ij} A_j$$

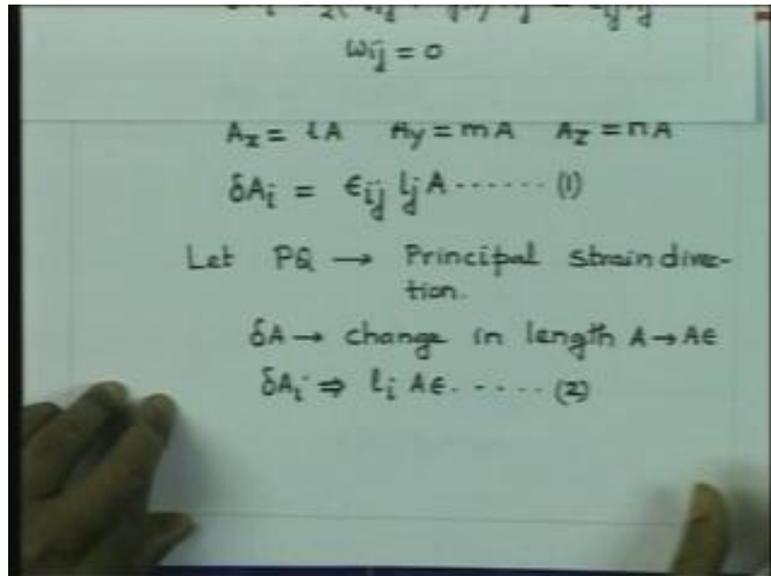

$$\omega_{ij} = 0$$

Now, this can be written also making use of the tensor relationship without detailing out, we can write it very in a compact form. u_{ij} is nothing but half of u_{ij} plus u_{ji} plus half of u_{ij} minus u_{ji} . So, you get now the strain tensor, you are already familiar that this is the definition of the strain tensor. And this is the definition of the rotation tensor ω_{ij} . For pure deformation, pure deformation we will have no rotation for pure deformation ω_{ij} is equal to 0. And therefore, we have u_{ij} is equal to u_{ji} .

Now, you would like to consider having got this affine transformation which is now possible to consider determination of the principle strains. So, will now consider

determination of principal strains. So, let us consider the determination of the principal strains. Now, for pure deformation we have δA_i is equal to $u_i j$ half of $u_i j + u_j i$ into A_j . Or you can write this thing as ϵ_{ij} into A_j . Since, w_{ij} is equal to 0. Now, let us consider that this P Q that we consider is having it is aligned with the direction.

(Refer Slide Time: 34:02)

So, the P Q is aligned with the directions with cosines l, m and n. Then, in that case we can write that A_x is equal to l into A, A_y is nothing but m into A and A_z is equal to n into A. Therefore, you can now write, we can write now that δA_i is equal to $\epsilon_{ij} l_j$ into A. Now, if P Q happens to be the principal strain direction. Let P Q rate principal strain direction.

So, if P Q is the principal direction, then we can write that the changes in length δA change in length of element P Q which is A is nothing but it is going to be A into ϵ . So, we can now write that δA_i is nothing but it is we can write then δA_i to the l_i into A into ϵ . So, we have already got δA_i equal to $\epsilon_{ij} l_j$ into A. And again we have then giving by this one. So, if you consider that this relationship, let us say it is 1, this relationship is 2.

(Refer Slide Time: 37:09)

$$\begin{aligned}
 l_j \epsilon_{ij} A - l_j \delta_{ij} A \epsilon &= 0 \dots (3) \\
 \left. \begin{aligned}
 l_1 \epsilon_{11} + l_2 \epsilon_{12} + l_3 \epsilon_{13} - l_1 \epsilon &= 0 \\
 l_1 \epsilon_{21} + l_2 \epsilon_{22} + l_3 \epsilon_{23} - l_2 \epsilon &= 0 \\
 l_1 \epsilon_{31} + l_2 \epsilon_{32} + l_3 \epsilon_{33} - l_3 \epsilon &= 0
 \end{aligned} \right\} \dots (3) \\
 \det | \epsilon_{ij} - \delta_{ij} \epsilon | &= 0 \dots (4) \\
 \Rightarrow \det | \sigma_{ij} - \delta_{ij} \sigma | &= 0 \text{ for } \sigma_{ij} \text{ stresses} \\
 (4) \rightarrow \epsilon^3 - J_1 \epsilon^2 - J_2 \epsilon - J_3 &= 0 \dots (5) \\
 J_1, J_2, J_3 \rightarrow \text{Strain invariants}
 \end{aligned}$$

Now, you can combine this two relations and you will get now that $l_j \epsilon_{ij} A - l_j \delta_{ij} A \epsilon$ is equal to 0. This ϵ stands for principal strain and l_j must also indicate that this A is the length of PQ . So, this particular relationship, it is very similar to what we have obtain in the case of principal stress.

So, if you expand it, you will find that, this is nothing but $l_1 \epsilon_{11} + l_2 \epsilon_{12} + l_3 \epsilon_{13} - l_1 \epsilon = 0$. And this is $l_1 \epsilon_{11} + l_2 \epsilon_{21} + l_3 \epsilon_{31} - l_1 \epsilon = 0$, $l_1 \epsilon_{21} + l_2 \epsilon_{22} + l_3 \epsilon_{23} - l_2 \epsilon = 0$, and $l_1 \epsilon_{31} + l_2 \epsilon_{32} + l_3 \epsilon_{33} - l_3 \epsilon = 0$. So, this is the expanded form of equation 3 let us indicate by 3 dash.

Now, this involves equation which can be written in a form like this, that the compact form is 3 and you say that here in we have the l_1, l_2, l_3 are the constant symbol, unknown constants. And this is the homogeneous set of equation right hand side is 0. And therefore, if it is to give us non zero solutions. Then, in that case we must have determinant of the quantity $\epsilon_{ij} - \delta_{ij} \epsilon$ must be equal to 0.

So, this is the characteristic equation. And it is similar to if you remember, in the case of stresses we had determinant of $\sigma_{ij} - \delta_{ij} \sigma$ equal to 0 for stresses for principal stresses. So, you have got a closely parallel relationship for the principal strains.

And this relation is going to again before can be expanded it is going to be of a form $\epsilon_j^3 - \epsilon_j^2 - \epsilon_j = 0$. This is the cubic equation, involving the principal strain and this $\epsilon_1, \epsilon_2, \epsilon_3$ are called strain invariants, similar to stress invariants they are also strain invariants.

And they will be obtainable from the strain component. And they will have closely parallel relationship. And with this you can find out the three principal strains. And for each of the principal strains, you can come back to this relationship $\epsilon_j^3 - \epsilon_j^2 - \epsilon_j = 0$ to get the corresponding directions. So, that is how you can determine the principals strains and their directions.

(Refer Slide Time: 42:25)

DEVIATORIC STRAINS, HYDROSTATIC/
SPHERICAL / VOLUMETRIC STRAINS

$$\epsilon_{ij} = \epsilon_{ij} - \delta_{ij} \epsilon_m + \delta_{ij} \epsilon_m$$

$$\epsilon_m = \epsilon_{ii}/3 = (\epsilon_x + \epsilon_y + \epsilon_z)/3$$

$$\epsilon_{ij} = \underbrace{\epsilon_{ij}'}_{\text{Deviatoric}} + \underbrace{\delta_{ij} \epsilon_m}_{\text{Hydrostatic}}$$

Similarly, we can also consider the deviatoric strains. So, deviatoric strains in close parallel to deviatoric stress, we can have deviatoric strains. Then, we can have also hydrostatic strains, deviatoric strains and hydrostatic spherical volumetric strain. So, we would like to now break the total strains into deviatoric and volumetric strains.

And obviously, we can have $\epsilon_{ij} = \epsilon_{ij} - \delta_{ij} \epsilon_m + \delta_{ij} \epsilon_m$. This ϵ_m is nothing but the mean stress mean normal stress and this is given by $\epsilon_{ii}/3$. And therefore, this is nothing but $\epsilon_x + \epsilon_y + \epsilon_z$ divided by 3.

And we can represent ϵ_{ij} in this form $\epsilon_{ij} + \delta_{ij} \epsilon_{kk}$ varying, this is known as deviatoric strain tensor. And this one is known as volumetric or hydrostatic strain tensor or spherical strain tensor. So, we will write this thing as hydrostatic strain tensor. There are certain typical it is, which are associated with the strains. And we would like to look into the typical it is, this are known as strain compatibility conditions.

(Refer Slide Time: 46:01)

COMPATIBILITY CONDITIONS

$$\epsilon_x = \frac{\partial u}{\partial x} \quad \epsilon_y = \frac{\partial v}{\partial y} \quad \gamma_{xy} = \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x}$$

$$\frac{\partial^2 \gamma_{xy}}{\partial x \partial y} = \frac{\partial^3 u}{\partial x \partial y^2} + \frac{\partial^3 v}{\partial y \partial x^2}$$

$$= \frac{\partial^2}{\partial y^2} \left(\frac{\partial u}{\partial x} \right) + \frac{\partial^2}{\partial x^2} \left(\frac{\partial v}{\partial y} \right)$$

$$\frac{\partial^2 \gamma_{xy}}{\partial x \partial y} = \frac{\partial^2 \epsilon_x}{\partial y^2} + \frac{\partial^2 \epsilon_y}{\partial x^2}$$

Similarly, $\frac{\partial^2 \gamma_{yz}}{\partial y \partial z} = \frac{\partial^2 \epsilon_y}{\partial z^2} + \frac{\partial^2 \epsilon_z}{\partial y^2}$

We had already got the expression for strains like $\epsilon_x = \frac{\partial u}{\partial x}$ and $\epsilon_y = \frac{\partial v}{\partial y}$. And then, we have $\gamma_{xy} = \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x}$. Now, you see that the three strain components are defined by the two displacement functions.

Now, if you try to take the second derivative of this, if you differentiate this with respect to x and y separately. Then, what will have is $\frac{\partial^2 \gamma_{xy}}{\partial x \partial y}$. So, we will have this thing as $\frac{\partial^3 u}{\partial x \partial y^2} + \frac{\partial^3 v}{\partial y \partial x^2}$. So, this is $\frac{\partial^2}{\partial y^2} \left(\frac{\partial u}{\partial x} \right) + \frac{\partial^2}{\partial x^2} \left(\frac{\partial v}{\partial y} \right)$.

So, we have now this is nothing but $\frac{\partial^2 \epsilon_x}{\partial y^2} + \frac{\partial^2 \epsilon_y}{\partial x^2}$. So, we can write now $\frac{\partial^2 \gamma_{xy}}{\partial x \partial y} = \frac{\partial^2 \epsilon_x}{\partial y^2} + \frac{\partial^2 \epsilon_y}{\partial x^2}$. So therefore, this is the compatibility condition, you see that here we have the derivative $\frac{\partial^2 \gamma_{xy}}{\partial x \partial y}$ this is the ((Refer Time: 48:50)). And this is

the related Epsilon x and the derivative is twice with respect to y and here it is Epsilon y and the derivative with respect to x.

So, this is known as the compatibility conditions strain compatibility conditions. If we now consider the other combination, we can have gamma y z and the strain Epsilon y Epsilon z by close parallel, we can get delta 2 gamma y z derivative should be with respect to y and z. This must be equal to delta 2 delta z square it must be Epsilon y delta 2 delta y square Epsilon z.

(Refer Slide Time: 50:03)

The image shows a whiteboard with handwritten mathematical derivations for strain compatibility conditions in three dimensions. The equations are as follows:

$$\frac{\partial^2 \gamma_{zx}}{\partial z \partial x} = \frac{\partial^2 \epsilon_x}{\partial z^2} + \frac{\partial^2 \epsilon_z}{\partial x^2}$$

$$2 \frac{\partial^2 \epsilon_z}{\partial y \partial z} = \frac{\partial}{\partial x} \left(-\frac{\partial \gamma_{yz}}{\partial x} + \frac{\partial \gamma_{zx}}{\partial y} + \frac{\partial \gamma_{xy}}{\partial z} \right)$$

$$2 \frac{\partial^2 \epsilon_y}{\partial x \partial z} = \frac{\partial}{\partial x} \left(\frac{\partial \gamma_{yz}}{\partial x} - \frac{\partial \gamma_{zx}}{\partial y} + \frac{\partial \gamma_{xy}}{\partial z} \right)$$

$$2 \frac{\partial^2 \epsilon_z}{\partial x \partial y} = \frac{\partial}{\partial z} \left(\frac{\partial \gamma_{yz}}{\partial x} + \frac{\partial \gamma_{zx}}{\partial y} - \frac{\partial \gamma_{xy}}{\partial z} \right)$$

Ex. Prove $2 \frac{\partial^2 \epsilon_x}{\partial y \partial z} = \frac{\partial}{\partial x} \left(-\frac{\partial \gamma_{yz}}{\partial x} + \frac{\partial \gamma_{zx}}{\partial y} + \frac{\partial \gamma_{xy}}{\partial z} \right)$

So, this is the second strain compatibility conditions, in three dimension and the third one we can write now delta 2 gamma z x delta z delta x is equal to delta 2 delta z square Epsilon x plus delta 2 Epsilon z delta x square. So, this three relations are known as three compatibility conditions in three dimensions. And if we have two dimensions, we are going to simply have this one strain compatibility conditions.

It can be also shown that we will have another set of compatibility conditions. We will consider now, this relationships are delta 2 Epsilon x delta y delta z is equal to delta delta x minus delta gamma y z delta x plus delta gamma z x delta y plus delta gamma x y delta z. So, this is another strain compatibility conditions.

And the other two which are of the similar type delta 2 Epsilon y delta x delta z delta delta x delta gamma y z delta x minus delta gamma z x delta y plus delta gamma x y

δz . And the last one $\delta^2 \epsilon z \delta x \delta y$ is equal to $\delta \delta z \delta \gamma y z \delta x$ plus $\delta \delta z \delta \gamma z x \delta y$ minus $\delta \delta z \delta \gamma x y \delta z$. This compatibility conditions can also be derived starting from the strains.

So, what we find is that we have the strains satisfying some constants conditions, they are three in this form and the other three are going to be in this form. Now, it will be good idea for you to see, how this condition can be derived. Now, if you try to consider... So, let us take as an example how to derive the compatibility conditions, which is shown here.

So therefore, prove $\delta z \delta \delta x$ minus $\delta \delta \gamma y z \delta x \delta \delta z$ plus $\delta \delta \gamma z x \delta y$ by δz . You not of to do this, what you have to do? You just take the expression for $\delta \delta \gamma x y$ differentiate with respect to z . And then, take the expression for $\delta z x$ differentiate with respect to y . And similarly take the expression for $\delta \delta \gamma y z$ and differentiate with respect to x .

And then, take the sum and once you take that sum, you will find that you are going to have a relationship involving some expression, which will finally, lead to this left hand side. So, you try to take the expression for the strains $\delta \delta \gamma x y$ $\delta \delta \gamma z x$ $\delta \delta \gamma y z$, separately. And differentiate them as shown here some them up. Then, once you differentiate this resultant expression with respect to x , you are going to get the left hand side.
