**Model Reference Adaptive Control: Lyapunov Stability Analysis**

Hello everyone, welcome to yet another session of our NPTEL on Non-Linear and Adaptive Control, I am Srikant Sukumar from Systems and Control, IIT, Bombay. We are into the 8th week of our lectures on Non-Linear Adaptive Control. And we are already well underway into designing algorithms that can drive systems such as the spacecraft orbiting the earth, which we see in the background.

(Refer Slide Time: 0:55)

**2 Model Reference Adaptive Control**

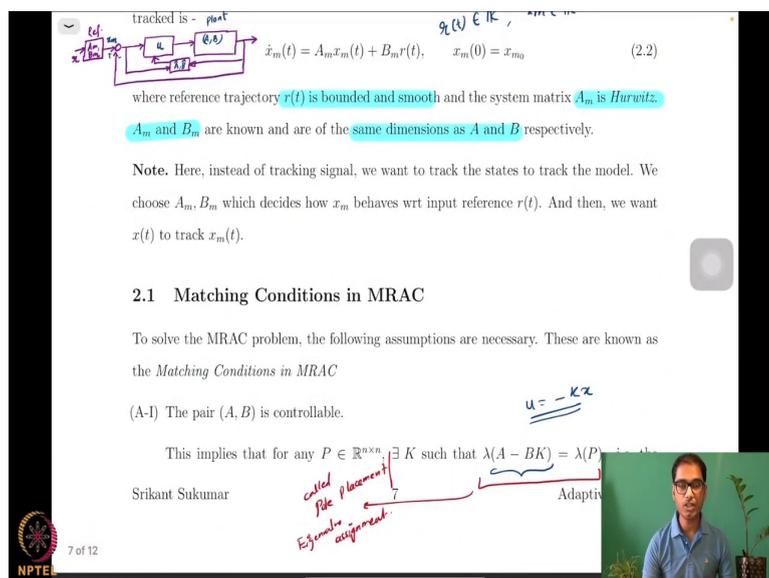

We consider the case of a general linear time-invariant system with unknown parameters. The system is required to follow the states of a *Reference Model* whose parameters and inputs are known. This type of problem is called *Model Reference Adaptive Control* (MRAC). The system to be controlled is -

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = x_0, x \in \mathbb{R}^n, u \in \mathbb{R}^m \quad (2.1)$$

where  $A \in \mathbb{R}^{n \times n}$  and  $B \in \mathbb{R}^{n \times m}$  are unknown constant matrices. The reference model tracked is -

$$\dot{x}_m(t) = A_m x_m(t) + B_m r(t), \quad x_m(0) = x_{m0}$$

where  $r(t) \in \mathbb{R}^m, x_m \in \mathbb{R}^n$

where reference trajectory  $r(t)$  is bounded and smooth and the system matrix  $A_m$  is Hurwitz.  $A_m$  and  $B_m$  are known and are of the same dimensions as  $A$  and  $B$  respectively.

**Note.** Here, instead of tracking signal, we want to track the states to track the model. We choose  $A_m, B_m$  which decides how  $x_m$  behaves wrt input reference  $r(t)$ . And then, we want  $x(t)$  to track  $x_m(t)$ .

**2.1 Matching Conditions in MRAC**

To solve the MRAC problem, the following assumptions are necessary. These are known as the *Matching Conditions in MRAC*

(A-1) The pair  $(A, B)$  is controllable.

This implies that for any  $P \in \mathbb{R}^{n \times n}, \exists K$  such that  $\lambda(A - BK) = \lambda(P)$

Srikant Sukumar

Adaptive

7 of 12

be matched, not the matrices themselves.

(A-III)  $\exists L^* \in \mathbb{R}^{m \times m}$  such that  $D\dot{f} = B_m, L^* = L^{*T}$ .

*Justification: Flexibility in choosing  $B_m$  simplest situation  $L^* = \epsilon I$   
 $B_m = \epsilon B$*

Here,  $L^*$  is symmetric and sign-definite.

(A-IV)  $\text{sgn}(L^*)$  as defined below is assumed to be known.

$$\text{sgn}(L^*) = \begin{cases} +1, & L^* > 0 \\ -1, & L^* < 0 \end{cases} \quad (2.3)$$

*Lechuse 8.1*

## 2.2 Certainty Equivalence Approach

### 2.2.1 Known Parameter Case

As in the case of the scalar system, a control is developed for the case where the parameters of the plant are assumed to be known exactly as follows:

$$u(t) = -K^*x(t) + L^*r(t)$$

Now, defining -

$$e(t) = x(t) - x_m(t)$$

we have -

$$\dot{e}(t) = \dot{x}(t) - \dot{x}_m(t)$$

$$= A_m x(t) + B_m r(t) - A_m x_m(t) - B_m r(t)$$

$$= (A_m x(t) + B_m r(t) - A_m x_m(t) - B_m r(t))$$

$$\dot{e}(t) = A_m e(t)$$

*Am Hurwitz,  $Q = Q^T > 0, \exists P = P^T > 0$ ,  $\uparrow$  Lyapunov eqn*

*$\dot{V} = e^T P \dot{e} + \dot{e}^T P e = e^T (P A_m + A_m^T P) e = -e^T Q e < 0$*

which is a Hurwitz system, and so,  $e(t)$  goes to zero exponentially.

**Note.** We have moved from unknowns  $A$  and  $B$  to  $K^*$  and  $L^*$ . This is similar to the scalar case, where we moved from unknowns  $a$  and  $b$  to  $\theta_1^*$  and  $\theta_2^*$ .

### 2.2.2 Unknown Parameter Case

As in the scalar system case, the parameters in the control law for the known case,  $K^*, L^*$  are replaced by their estimates using the CE principle.

*unknowns or matrices  $\in \mathbb{R}^{m \times n}, \in \mathbb{R}^{m \times m}$*

So, last time we started to look at model reference adaptive control. We already introduced the problem, in the previous week along with the assumptions and of course the matching conditions which are very very critical. Subsequently we started the design for the adaptive controller in the usual approach of starting with the known parameter case, and then of course moving on to the unknown case via the certainty equivalence approach.

The difference of course is how we chose the target system. So, the target system was in this case chosen in a very very smart way and was inspired from the reference model itself. So, this was what helped us to design the controller for the known case and of course going from the known to the unknown case was it is always very easy because we just simply apply the certainty equivalence principle.

So, that is really the trick. We apply the certainty equivalence principle in order to go from the known to the unknown case.

(Refer Slide Time: 2:16)

Plugging this into (2.1), we have -

$$\begin{aligned}\dot{x}(t) &= Ax(t) + Bu(t) \\ &= (A_m + BK^*)x(t) + B(-\hat{K}x(t) + \hat{L}r(t)) + \underbrace{(B_m - BL^*)}_{=0}r(t) \\ &= (A_m + B\tilde{K})x(t) + (B_m - B\tilde{L})r(t)\end{aligned}$$

where

$$\begin{aligned}\tilde{K} &= K^* - \hat{K} \\ \tilde{L} &= L^* - \hat{L}\end{aligned}$$

This gives us the following error dynamics -

$$\begin{aligned}\dot{e}(t) &= \dot{x}(t) - \dot{x}_m(t) \\ &= (A_m + B\tilde{K})x(t) + (B_m - B\tilde{L})r(t) - A_m x_m(t) - B_m r(t)\end{aligned}$$

This gives us the following error dynamics -

$$\begin{aligned}\dot{e}(t) &= \dot{x}(t) - \dot{x}_m(t) \\ &= (A_m + B\tilde{K})x(t) + \cancel{(B_m - B\tilde{L})}r(t) - A_m x_m(t) - \cancel{B_m}r(t)\end{aligned}$$

So, we have -

$$\dot{e}(t) = A_m e(t) + B(\tilde{K}x(t) - \tilde{L}r(t)) \quad (2.7)$$

Now, we define some new matrices -

*b = \text{sgn}(\omega) |b|*  $\rightarrow$   $\Gamma$  is unknown

$$\begin{aligned}\Gamma &= \text{sgn}(L^*)L^{*-1} \quad (\Rightarrow \Gamma = \Gamma^T, \Gamma > 0) \\ B &= B_m L^{*-1} = \text{sgn}(L^*)B_m \Gamma\end{aligned}$$

Now the difference, now that becomes apparent to us is that the parameters are not the scalars or vectors but in fact they are matrices. So, it is K tilde and L tilde and K star and L star which are all matrices we have already made an assumption that we know the sign of L star. So, L star is symmetric definite and we know whether it is positive definite or negative definite.

So, using this fact that we know the sign of L star we define a matrix gamma which is positive definite symmetric, which will appear sort of frequently in the Lyapunov analysis.

(Refer Slide Time: 3:09)

5:38 PM Mon 16 May

Adaptive\_Control\_Week8

Substituting in (2.7), we have -

$$\dot{e}(t) = A_m e(t) + \text{sgn}(L^*) B_m \Gamma (\hat{K}x(t) - \tilde{L}r(t)) \quad (2.8)$$

Now, since  $A_m$  is Hurwitz, given a  $Q$  such that  $Q = Q^T > 0$ ,  $\exists P = P^T > 0$  satisfying the Lyapunov Equation -

$$A_m^T P + P A_m = -Q \quad (2.9)$$

**2.2.3 Lyapunov function**

We choose our Lyapunov function to be -

*Handwritten notes:*  
 $\text{tr}(M^T M) = \text{tr}(M M^T)$   
 $\hookrightarrow$  Frobenius norm  
 $\text{tr}(M) = \sum_{i=1}^n m_{ii}$

5:38 PM Mon 16 May

Adaptive\_Control\_Week8

Substituting in (2.7), we have -

$$\dot{e}(t) = A_m e(t) + \text{sgn}(L^*) B_m \Gamma (\hat{K}x(t) - \tilde{L}r(t)) \quad (2.8)$$

Now, since  $A_m$  is Hurwitz, given a  $Q$  such that  $Q = Q^T > 0$ ,  $\exists P = P^T > 0$  satisfying the Lyapunov Equation -

$$A_m^T P + P A_m = -Q \quad (2.9)$$

**2.2.3 Lyapunov function**

We choose our Lyapunov function to be -

$$V = e(t)^T P e(t) + \text{tr}(\hat{K}^T \Gamma \hat{K} + \tilde{L}^T \Gamma \tilde{L})$$

So,

$$V(e, \hat{K}, \tilde{L}) = 0 \Leftrightarrow e, \hat{K}, \tilde{L} \equiv 0$$

else  $V(e, \hat{K}, \tilde{L}) > 0$

*Handwritten notes:*  
 $\text{tr}(M^T M) = \text{tr}(M M^T)$   
 $\hookrightarrow$  Frobenius norm  
 $\text{tr}(M) = \sum_{i=1}^n m_{ii}$   
 $M \in \mathbb{R}^{n \times n}$

*So*

$$\dot{V} = e(t)^T P \dot{e}(t) + \dot{e}(t)^T P e(t) + \text{tr}(\dot{\hat{K}}^T \Gamma \hat{K} + \hat{K}^T \Gamma \dot{\hat{K}} + \dot{\tilde{L}}^T \Gamma \tilde{L} + \tilde{L}^T \Gamma \dot{\tilde{L}})$$

5:43 PM Mon 16 May

5:53 PM Mon 16 May

Adaptive\_Control\_Week8

So,  $v(e, \tilde{K}, \tilde{L}) = 0 \Leftrightarrow e, \tilde{K}, \tilde{L} = 0$  else  $v(e, \tilde{K}, \tilde{L}) > 0$

$\dot{V} = e(t)^T P e(t) + \dot{e}(t)^T P e(t) + 2 \text{tr}(\tilde{K}^T \Gamma \dot{\tilde{K}} + \tilde{L}^T \Gamma \dot{\tilde{L}})$  *elem chng*  
 $= e(t)^T P (A_m e(t) + \text{sgn}(L^*) B_m \Gamma (\tilde{K} x(t) - \tilde{L} r(t)))$  *tr(M) = tr(M^T)*  
 $+ (A_m e(t) + \text{sgn}(L^*) B_m \Gamma (\tilde{K} x(t) - \tilde{L} r(t)))^T P e(t) - 2 \text{tr}(\tilde{K}^T \Gamma \dot{\tilde{K}} + \tilde{L}^T \Gamma \dot{\tilde{L}})$  *tr(AB^T) = tr(B^T A)*  
 $= -e(t)^T Q e(t) + 2 \text{sgn}(L^*) e(t)^T P B_m \Gamma (\tilde{K} x(t) - \tilde{L} r(t)) - 2 \text{tr}(\tilde{K}^T \Gamma \dot{\tilde{K}} + \tilde{L}^T \Gamma \dot{\tilde{L}})$

Using the property of 2 vectors  $u$  and  $v$  - *appears somewhere in the middle.*  
 $u, v \in \mathbb{R}^k$   
 $u^T v = \text{tr}(uv^T)$   
 $\therefore \text{tr}(uv^T) = \text{tr}(v^T u)$

Srikant Sukumar 11

5:46 PM Mon 16 May

Adaptive\_Control\_Week8

we have -

$\dot{e}(t) = \dot{x}(t) - \dot{x}_m(t)$

$\dot{e}(t) = \dot{x}(t) - \dot{x}_m(t) = A_m x(t) + B_m r(t) - A_m x_m(t) - B_m r(t)$

$\dot{e}(t) = A_m e(t)$

*Am Hurwitz*  
 $\exists P = P^T > 0, \exists Q = -P A_m$   
 $\exists \gamma > 0, \exists \beta > 0$   
 $\exists \gamma > 0, \exists \beta > 0$   
 $\exists \gamma > 0, \exists \beta > 0$

which is a Hurwitz system, and so,  $e(t)$  goes to zero exponentially.

Note. We have moved from unknowns  $A$  and  $B$  to  $K^*$  and  $L^*$ . This is similar to the scalar case, where we moved from unknowns  $a$  and  $b$  to  $\theta_1^*$  and  $\theta_2^*$ .

2.2.2 Unknown Parameter Case

As in the scalar system case, the parameters in the control law for the known case,  $K^*, L^*$  are replaced by their estimates using the CE principle.

So, using this gamma we now write our closed loop dynamical system in this particular form. So, this is the form that we would have obtained if there was a no parameter error or for the case when we do know the parameter. This is exactly what would be the closed loop dynamics but because we do not know the parameter there are terms in the parameter errors which is what you have commonly adaptive control.

And we choose a corresponding Lyapunov function using the fact that  $A_m$  is a Hurwitz matrix and just like you would have used the norm a square norm for the vector case or just a square for the scalar case, we use a sort of norm a weighted norm for this matrix case also and this is defined via the trace of the matrix  $K$  tilde transpose gamma  $K$  tilde and similarly  $L$  tilde transpose gamma  $L$  delta. So, this is where we were.

So, I am going to mark the beginning here as lecture 8.2. So, I am going to mark this as lecture 8.2. So, this we already saw last time is in fact a valid Lyapunov function in fact it can be very easily claimed to be strictly positive definite also. So, no worries there we also know what is the trace operation it is essentially the sum of the diagonal elements of a matrix.

We also have certain nice properties of the trace like I mean it does not matter if you do the inner product or the outer product, the trace remains the same in fact does not have to be the same matrices either. So, you can change the sequence of things and the trace does not change and that is really what is important and we will in fact exploit this property.

So, one of the very very key properties of the trace like I said here but I can write it in a different color is the trace of  $A B^T$  is equal to trace of  $B^T A$  basically it is agnostic to the sequence in which I do things.

So, I can do  $A B^T$  or you can do  $B^T A$  and vice versa the trace is not going to change. So, this is one of the very very key properties that we will exploit soon. So, now let us take the derivative just like we do all let us diligently take the derivative and plug in the closed loop dynamics. So, we are yet to choose of course the update loss for the  $K$  tildes and  $L$  tilda's and that is really what we are trying to do with this Lyapunov analysis.

So,  $\dot{V}$  now remember these are vector operations we have to be very careful. So, because it is a vector. So, I take the derivative of all the terms very carefully. So, first I have  $e^T P e$  basically taking the derivative of this, and then using the product rule I have to take the derivative of this term, so  $e^T \dot{P} e$ .

And now in this one I just say twice trace of derivatives here. Honestly speaking I could have written this also in this way, that is I could have written I mean let me actually sort of make this a little bit more clear. So,  $d/dt$  of trace of say  $K^T \dot{\gamma} K$  would have been written as trace of  $K^T \dot{\gamma} K$  plus trace of  $K^T \gamma \dot{K}$ , I could have done this I could have done this.

But the point is that because this entire thing is in fact a scalar. So, I am free to take a transpose I am free to take a transpose and of course transpose of I mean it is also true which I hope it is also evident to you that transpose of  $M$  sorry trace of  $M$  is equal to trace of  $M^T$ . So, the trace does not modify under the transpose.

So, if I take the transpose here I would get if I take the transpose here in fact I would get trace of  $K^T \dot{\gamma} K$  which is actually the same as this, which is actually

the same of this. And that is why I am directly writing this as twice trace this. In fact I could have pretty much done the same thing here too let us be clear I could have done the same thing here too because  $P$  is a symmetric matrix.

So, I could have taken the transpose of this and I would have obtained  $e^T P e$  which is the same as this but I am simply writing this separately because I am going to use the Lyapunov equation. That is it, that is the only reason I am not doing anything magical here. This could also be written as twice  $e^T P e$ . Why?

Because this is a scalar, this is a scalar, transpose of a scalar is the same scalar. Therefore, I am free to take transpose of any term this is this we this is a trick we use regularly in all our Lyapunov analysis for vector equations.  $V$  is a scalar, so each term is a scalar. Therefore, I am free to take the transpose of any scalar term because it yields the same scalar term because I can take transpose of a scalar I end up with the same scalar nothing changes.

So, if I take the transpose of this term I get  $e^T P^T e$ . But because  $P$  is a symmetric matrix I get  $e^T P e$ . So,  $e^T P^T e$  is the same as  $e^T P e$  which is the same as this term. So, I could have written this very well as twice  $e^T P e$  I simply am not choosing not to write it in that way because I want to write the Lyapunov equation or use the Lyapunov equation.

So, what is this? So, when I substitute for  $\dot{e}$  now in on both sides here, so this remains as it is for a while, this remains as it is I just use the fact that  $\tilde{K} \dot{e}$  is equal to  $-\hat{K} \dot{e}$  and that is what shows up here and that is it. So, again I have flipped it here, this is flipped here, and this is also flipped here do not mind I can flip as many times as I want it does not change anything because trace of  $A$  is equal, trace of  $M$  is equal to trace of  $M^T$ .

So, these terms remain as it is just with the negative sign because the  $\tilde{K} \dot{e}$  has been changed to  $\hat{K} \dot{e}$ . And similarly,  $\tilde{L} \dot{e}$  has been changed to  $\hat{L} \dot{e}$  that is what is bringing up the negative sign. So, so let us see, so then what do we do, we basically plug in for the dynamics  $\dot{e}$  that is a closed loop dynamics  $\dot{e}$  from here, that is what you see here, that is it.

It is  $A_m e + \text{sgn } L^* B_m \gamma$  this thing and similarly here with the transpose this guy. Now these terms and this term gets combined to give me this term this is just the Lyapunov equation. So, if you may, this term, this term with this term, whatever gets combined and can

be written as  $e^T P A_m$  plus  $A_m^T P e$  and that is actually equal to minus  $e^T Q e$  from the Lyapunov equation corresponding to the  $A_m$ , which is a Hurwitz or stable matrix.

Now, so that is how I get this nice negative term this is the nice negative definite term that we are always looking out for in the Lyapunov analysis. So, we already have that term and why this is because we chose a nice target system. So, we chose this as a target system and that is why we get this nice negative term and  $A_m$  is a Hurwitz matrix.

So, then we if you look at the rest of the terms all the terms that remain which is these guys, these guys these are all parameter error terms. So, again this term and this term can also be combined similarly this term and this term can also be combined and that is what is being done here. These are combined to write them as two  $\text{sgn } L^T e^T P B_m \gamma$  and this.

Both these terms are exactly the same, both these terms are, again using the logic that  $V$  is a scalar, so every term is a scalar therefore I can take transposes as many times as I want. So, so this term combines with this term to give us this two times term. And we also have the same two coefficient here as you would expect and in this form.

Now if you see we have a little bit of a funny situation here, earlier when we were doing all this parameter update law design, we would always get a  $\tilde{\theta}$  common on the left hand side and all that because it was a scalar, so we could move the  $\tilde{\theta}$  anywhere. Now the problem that we have here is that the  $\tilde{K}$  which we want to take common outside is somewhere in the middle and these are all matrices.

So, it is not like I can move it to the left and right arbitrarily. So, this is important to note. So, this term and this term. So,  $\tilde{K}$  appears somewhere in the middle we would ideally want it to be on the left or the hand side. So, that we can take things common and whatever cancel it out using  $\hat{K} \dot{\tilde{\theta}}$  this is what we have been doing, now what do we do, well, we use nice tricks from the trace properties.

So, this this is where we see one another trace property. So, we already know this that trace of  $M$  is the trace of  $M^T$  and trace of  $A B^T$  is trace of  $B^T A$ . In fact from these two I can derive this. So, if you, so here we are saying that trace of  $u^T v$  where both  $u$  and  $v$  are vectors are vectors is the same as trace of  $u v^T$ .

So, basically if you have vectors of the same dimension, so  $u$   $v$  has to be vectors in some  $\mathbb{R}^k$  has to be the same dimension otherwise inner product is not different. And you take the inner product that is  $u^T v$  then this is the same as trace of the outer product. So, notice that this is a scalar and this is an  $n$  by  $n$  matrix or a  $k$  by  $k$  matrix and because I take a trace it becomes a scalar. So, both sides are scalar.

So, this one needs to verify of course for our own sanity and then we can try to use these results let us try I do not know I mean maybe we maybe it works maybe it does not work. So, so let us see. So, this is actually equal to trace of  $u^T v$  it is a scalar. So, this is also the same as trace of  $v^T u$  because that is the same scalar take a transpose of a scalar I say that get the same scalar and the trace of a scalar is also the same scalar because scalar can be seen as a trivial matrix of a 1 by 1 matrix.

So, the sum of diagonals is just the scalar itself. So,  $u^T v$  is the same as trace  $u^T v$  and trace  $u^T v$  is the same as trace  $v^T u$  because again we are just transposing it using this identity. And then finally I can flip the order I am allowed to flip the order of the operation with the trace this is the from this property. So, this this whatever this property that you have can be obtained from the other properties that we already had.

So, this is not a new property per se, it is in fact just something that is derived from the existing property. So, these two are the most key ones if you remember these you can mostly derive the other important trace equalities. So, now we have this very nice trace equality that the inner product is equal to the trace of the outer product of vectors and that is what we are going to apply to these terms this term and then this term.

(Refer Slide Time: 19:01)

We have -

$$\dot{e}(t)^T P B_m \Gamma \hat{K} x(t) = \left( \hat{K}^T \Gamma B_m^T P e(t) \right)^T x(t) = \text{tr} \left( \hat{K}^T \Gamma B_m^T P e(t) x(t)^T \right)$$

$$\dot{e}(t)^T P B_m \Gamma \hat{L} r(t) = \left( \hat{L}^T \Gamma B_m^T P e(t) \right)^T r(t) = \text{tr} \left( \hat{L}^T \Gamma B_m^T P e(t) r(t)^T \right)$$

Substituting in the  $\dot{V}$  equation, we have -

$$\dot{V} = -e(t)^T Q e(t) + 2 \text{tr} \left( \hat{K}^T \Gamma \left( \text{sgn}(L^*) B_m^T P e(t) x(t)^T - \hat{K} \right) \right) + 2 \text{tr} \left( \hat{L}^T \Gamma \left( -\text{sgn}(L^*) B_m^T P e(t) r(t)^T - \hat{L} \right) \right)$$

Now, choosing -

$$\begin{aligned} \dot{\hat{K}} &= + \text{sgn}(L^*) B_m^T P e(t) x(t)^T \\ \dot{\hat{L}} &= - \text{sgn}(L^*) B_m^T P e(t) r(t)^T \end{aligned}$$

$$\begin{aligned} \dot{\hat{K}} &= + \text{sgn}(L^*) B_m^T P e(t) x(t)^T \\ \dot{\hat{L}} &= - \text{sgn}(L^*) B_m^T P e(t) r(t)^T \end{aligned} \quad (2.11)$$

Thus, we get -

$$\dot{V} = -e(t)^T Q e(t) \quad (2.12)$$

Since  $Q > 0$ ,  $\dot{V} \leq 0$  and hence the error signal can be shown to be asymptotically approaching zero by signal chasing. It can also be shown that the estimates  $\hat{K}$  and  $\hat{L}$  are bounded signals. Equations (2.6), (2.11) form the adaptive control law which guarantees model reference tracking.

$$\frac{d}{dt} (e, \tilde{K}, \tilde{L}) = \begin{pmatrix} \dots \\ \dots \\ \dots \end{pmatrix} (e, \tilde{K}, \tilde{L})$$

Srikanth Sukumar 12 Adaptive

So,

$$\dot{V} = e(t)^T P e(t) + \dot{e}(t)^T P e(t) + 2 \text{tr} \left( \hat{K}^T \Gamma \hat{K} + \hat{L}^T \Gamma \hat{L} \right) \dot{e}(t)^T P e(t) = \text{tr} \left( \hat{K}^T \Gamma \hat{K} \right) \dot{e}(t)^T P e(t) + \text{tr} \left( \hat{L}^T \Gamma \hat{L} \right) \dot{e}(t)^T P e(t)$$

$$= e(t)^T P \left( A_m e(t) + \text{sgn}(L^*) B_m \Gamma \left( \hat{K} x(t) - \hat{L} r(t) \right) \right) + \left( A_m e(t) + \text{sgn}(L^*) B_m \Gamma \left( \hat{K} x(t) - \hat{L} r(t) \right) \right)^T P e(t) - 2 \text{tr} \left( \hat{K}^T \Gamma \hat{K} + \hat{L}^T \Gamma \hat{L} \right) \dot{e}(t)^T P e(t)$$

$$= -e(t)^T Q e(t) + 2 \text{sgn}(L^*) e(t)^T P B_m \Gamma \left( \hat{K} x(t) - \hat{L} r(t) \right) - 2 \text{tr} \left( \hat{K}^T \Gamma \hat{K} + \hat{L}^T \Gamma \hat{L} \right) \dot{e}(t)^T P e(t)$$

Using the property of 2 vectors  $u$  and  $v$  -

$$u, v \in \mathbb{R}^k$$

$$u^T v = \text{tr}(uv^T)$$

$$\text{tr}(uv^T) = \text{tr}(v^T u)$$

$$\text{tr}(v^T u) = \text{tr}(u v^T)$$

We do the same thing on the other term that is also a similar term it is if I ignore this because this is just a scalar and can be moved around. So, I do not need to worry about this. I look at the second term which is  $e^T P B m \gamma L^T r$   $e^T P B m \gamma L^T r$ . So, similarly I think of this term everything before the  $r$  everything before the  $r$  is my  $u$  transpose.

So, again this is  $u$  and so this is  $u^T v$  and this is essentially trace of  $u v^T$ . So, what does this do notice in this expression  $K^T$  is somewhere in between of no use to us but in this new expression  $K^T$  is all the way to the left and the trace appears. So, earlier there was no trace either. So, and why do we need the trace?

Because the comparison term in  $K^T$  contains the trace or is within the trace. So, obviously I need somehow the trace function to appear here and I also want the  $K^T$  to be somewhere in the left because here the  $K^T$  appears in the left. Similarly, for the  $L^T$  here it is somewhere in the middle with no trace.

So, I want this to appear in the left inside the trace function and that is exactly what happens this appears inside a trace function there is a  $K^T$  transpose in the beginning and then again a trace function and then  $L^T$  transpose in the beginning. So, we essentially substitute back into this this back into the  $V$  dot equation I am again left with this nice negative definite term then I have a twice trace  $\text{sgn } L^*$  is remaining as it is.

And then I have taken because this is a scalar I can move it around wherever I want. So, I move it inside here then I take the  $K^T \gamma$  out. So, I get a  $\text{sgn } L^*$  here from this term  $\text{sgn } L^* B m^T P e^x$ . So, I cannot change the sequence of the matrices. So, this is fine and notice there is a  $K^T \gamma$  here, which I take common  $K^T \gamma$  here that is taken common.

So, I am left with this guy  $\text{sgn } L^*$  and this and a  $K^T$  here. Similarly, there is a notice that there is a  $L^T \gamma L^T \gamma$  here common. So, again  $L^T \gamma$  inside the trace common that is what I take out and then the  $\text{sgn } L^*$  is here of course that is a negative sign and then I am left with this term and then  $L^T$ .

So, this is just very careful bookkeeping now once I have applied this nice trick which gives me a trace and also pulls the  $K^T$  and  $L^T$  to the left most I can now take common with the terms here where the  $K^T$  and the  $L^T$  are in the left in fact I take both  $K^T$  and  $L^T \gamma$  common and  $L^T \gamma$  common.

And once I have this I am in good shape because now I can use my  $\hat{K}$  to cancel this guy similarly  $\hat{L}$  to cancel this guy which is exactly these equations brings about of course the sign of  $L^*$ . So, which is what we have already discussed that we do need to know the sign of  $L^*$ . So, we need to know whether it is positive definite or negative definite this condition or this requirement is exactly identical to knowing the sign of  $B$  in the scalar case nothing this is something we cannot avoid.

So, then you basically get rid of these terms and all you are left with is this guy and we know that this is because  $Q$  is positive definite  $\dot{V}$  is negative semi-definite not definite because we have additional states  $\tilde{K}$  and  $\tilde{L}$ . So, obviously it is not negative definite it is in fact negative semi definite.

So, what can we show? We can show that the error signal  $e$  goes to 0 asymptotically as  $t$  goes to infinity this we can do by signal chasing and using Barbalat's lemma. Of course also you can show that these are bounded signals no problem. Why? Because simply because  $V$  was chosen as a positive definite function containing both  $e$  quadratic essentially some kind of quadratic in  $e$   $\tilde{K}$  and  $\tilde{L}$  and we have also shown that  $\dot{V}$  is less than equal to zero. So,  $V$  is non-increasing function of time.

So, as time progresses  $V$  is non-increasing, which means that whatever is the initial value of  $V$  you cannot actually go beyond it therefore these things cannot go unbounded none of these terms can go unbounded and if none of these terms can go unbounded they are essentially norms which means  $e$   $\tilde{K}$   $\tilde{L}$  cannot go unbounded.

So, notice that we have used  $\gamma$  in the Lyapunov analysis but  $\gamma$  does not appear anywhere in the update law. It cannot because  $\gamma$  is unknown although we constructed this  $\gamma$  using this using this  $L^*$  inverse this is unknown therefore  $\gamma$  cannot appear anywhere in the update law. So, so again, so this is also again similar to this absolute value of  $B$  that we introduced in the Lyapunov function for the scalar case.

So, this is again something similar to that. So, so that is it. So, we are done we essentially have a nice model reference adaptive controller. This is what guarantees tracking of course it does not guarantee any kind of parameter identification again this is again I would say this is something that will that requires persistence of excitation.

And in fact I strongly recommend that you write the if you want to write the dynamical system in a very careful form with  $e$   $\tilde{K}$   $\tilde{K}$  and  $\tilde{L}$  as states if you write the

dynamical system in this form with some matrix. So,  $\dot{d}$  with some matrix  $e$  but I am writing it as a tuple (specif) very deliberately because  $K$  tilde and  $L$  tilde are matrices.

And  $e$  is a vector therefore you cannot actually write it in this form you have to vectorize  $K$  tilde and  $L$  tilde but if you do write it you will get appropriate conditions for persistence of excitation of a particular signal which will guarantee that parameters also converge asymptotically. So, this anyway we have seen this theory I would recommend that you write it in this form and see how it looks all but I mean we have perfect tracking which is what we typically guarantee in adaptive control anyway.

So, this was a model reference adaptive control. So, what we did today was complete the Lyapunov analysis for the model of preference adaptive control problem. And in the process of the Lyapunov analysis we learned a lot about trace and trace properties and how they can be used to construct a Lyapunov functions for matrix states.

We also learned about trace properties and how it can help us to manipulate the matrices that appear and move matrices from one location to another. So, that we can cancel some terms. So, we learned some interesting trace properties which are also very useful for a lot of different mathematical analysis and of course we were able to prescribe update loss for these matrix unknowns  $K$  tilde  $K$  star and  $L$  star.

And we were able to prove perfect tracking which is what we typically seek to guarantee in model reference adaptive control. So, that is sort of the exposition into model reference adaptive control for linear systems. We will now subsequently move into a new and different set of lectures where we will discuss some other and more novel topics. So, this is where we stop, thanks and I hope to see you again soon.
