**Important Aspects of Flow Modeling - I**

Good afternoon everyone. Today we will discuss some important aspects of flow modeling. Such aspects can be compared with the grammar of a language. If you want to enjoy creation of a given language, poems versus you have to know grammar in order to understand nuances of that language.

Similarly, if you want to model flows and heat transfer problems with greater competence, you required to understand some aspects of flow modeling and we will discuss those aspects today.

(Refer Slide Time: 01:22)

*Fluid Flow Modeling*

Before entering into the domain of actual flow modeling, we shall discuss some subtle points of fluid flow equations with the help of a model equation. The model equation should have convective, diffusive and time-dependent terms. Burgers (1948) introduced a simple nonlinear equation which meets the aforesaid requirements (Burger's equation).

$$\frac{\partial \zeta}{\partial t} + u \frac{\partial \zeta}{\partial x} = v \frac{\partial^2 \zeta}{\partial x^2}$$

Here,  $u$  is the velocity,  $v$  is the coefficient of diffusivity and  $\zeta$  is any property which can be transported and diffused. If the viscous term (diffusive term) on the right-hand side is neglected, the remaining equation may be viewed as a simple analog of Euler's equation.

$$\frac{\partial \zeta}{\partial t} + u \frac{\partial \zeta}{\partial x} = 0$$

Now we shall see the behavior of Burger's equations for different types of discretization methods. In particular, we shall study their influence on conservative and transportive property, and artificial viscosity.

$$\frac{\partial \zeta}{\partial t} + u \frac{\partial \zeta}{\partial x} = v \frac{\partial^2 \zeta}{\partial x^2}$$

where,  $u$  is the velocity,  $v$  is the diffusivity, and  $\zeta$  is any property which can be transported and diffused.

$$\frac{\partial \zeta}{\partial t} + u \frac{\partial \zeta}{\partial x} = 0$$

Before entering into the domain of actual flow modeling, I have already mentioned about it. So, we will learn this and here, we will take up a model equation, we will apply all our concepts, all our ideas on those model equations and we will see its character, we will see the result. Now, this model equation is called Burger's equation. Jan Burger very very well-known fluid dynamitist develop this equation, it is called one-dimensional Burger's equation.

It has all the components of full-fledged Navier-Stokes equations like this as you can see we have written the equation where  $u$  is the velocity and  $\nu$  is the coefficient of diffusivity or viscosity in case of modeling fluid flow problems and  $\zeta$  is the property that can be convicted and diffused and this is the temporal term.

Now, if the right-hand side is neglected, then the equation will behave as a simple analog of Euler's equation which will have temporal term and the advective term. So, some cases will include the diffusion, some cases we will only study the advection.

(Refer Slide Time: 03:46)

*Conservative property (contd.)*

Let us consider the vorticity transport equation

$$\frac{\partial \omega}{\partial t} = -(V \cdot \nabla) \omega + \nu \nabla^2 \omega \quad (1)$$

where  $\nabla$  is nabla or differential operator,  $V$  the fluid velocity and  $\omega$  the vorticity. If we integrate this over some fixed space region  $\mathcal{R}$  we get

$$\int_{\mathcal{R}} \frac{\partial \omega}{\partial t} d\mathcal{R} = - \int_{\mathcal{R}} (V \cdot \nabla) \omega d\mathcal{R} + \int_{\mathcal{R}} \nu \nabla^2 \omega d\mathcal{R}$$

The first term can be written as

$$\int_{\mathcal{R}} \frac{\partial \omega}{\partial t} d\mathcal{R} = \frac{\partial}{\partial t} \int_{\mathcal{R}} \omega d\mathcal{R}$$

Let us consider the vorticity transport equation

$$\frac{\partial \omega}{\partial t} = -(V \cdot \nabla) \frac{\partial \omega}{\partial x} + \nu \nabla^2 \omega \quad (1)$$

Where  $\nabla$  is nabla or differential operator,  $V$  the fluid velocity and  $\omega$  the vorticity.

Now, let us consider general vorticity transport equation. This is temporal derivative of vorticity equal to I have taken the convective term to the right-hand side so, minus sign has come, this is  $V \cdot \nabla$  which will give in Cartesian coordinate  $i \frac{\partial u}{\partial x} + j \frac{\partial u}{\partial y} + k \frac{\partial u}{\partial z}$  dot product of  $i$  into  $e$  plus  $j$  into  $v$  plus  $k$  into  $w$ .

So, that means, this operator is  $u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z}$  and it can be operated on velocity, temperature or vorticity. So, this is basically the convective term plus  $\nu \nabla^2 \omega$  which is diffusive term. I have written  $\lambda$  is differential operator,  $V$  is the velocity fluid and  $\omega$  is vorticity.

$$\int_{\mathcal{R}} \frac{\partial \omega}{\partial t} d\mathcal{R} = - \int_{\mathcal{R}} (V \cdot \nabla) \omega d\mathcal{R} + \int_{\mathcal{R}} \nu \nabla^2 \omega d\mathcal{R}$$

If we integrate it over a fixed region in space given by capital  $R$ , this is may be a volume, a fixed region described by a volume through which fluid is coming and you know going through. Now, we can see this is the; I mean we are then integrating the whole equation over the space variable  $R$  and we can get simply this equation.

The first term can be written as

$$\int_{\mathcal{R}} \frac{\partial \omega}{\partial t} d\mathcal{R} = \frac{\partial}{\partial t} \int_{\mathcal{R}} \omega d\mathcal{R}$$

Here, we will go term by term  $\frac{\partial \omega}{\partial t}$  integrated over space  $R$ , this since if we define a space and we are not changing the space with time so, this time derivative can be taken outside  $\frac{\partial}{\partial t}$  of  $\omega$  over the space  $R$  it is integrated.

(Refer Slide Time: 06:29)

*Conservative property (contd.)*

The second term may be expressed as

$$-\int_{\mathcal{R}} (V \cdot \nabla) \omega d\mathcal{R} = -\int_{\mathcal{R}} \nabla \cdot (V \omega) d\mathcal{R} = -\int_{A_0} (V \omega) \cdot n dA$$

We have invoked the relation  $\nabla \cdot (V \omega) = V \cdot (\nabla \omega) + \omega (\nabla \cdot V) \approx V \cdot \nabla \omega$  in above

Also, Gauss Divergence theorem has been applied.  $A_0$  is the boundary of  $\mathcal{R}$ ,  $n$  is unit normal vector and  $dA$  is the differential element of  $A_0$ . The remaining term of Eq. (1) may be written as

$$v \int_{\mathcal{R}} \nabla^2 \omega d\mathcal{R} = v \int_{A_0} (\nabla \omega) \cdot n dA$$

As because

$$v \int_{A_0} (\nabla \omega) \cdot n dA = v \int_{\mathcal{R}} \nabla \cdot (\nabla \omega) d\mathcal{R} = v \int_{\mathcal{R}} \nabla^2 \omega d\mathcal{R}$$

The second term can be expressed as

$$-\int_{\mathcal{R}} (V \cdot \nabla) \omega d\mathcal{R} = -\int_{\mathcal{R}} \nabla \cdot (V \omega) d\mathcal{R} = -\int_{A_0} (V \omega) \cdot n dA$$

$$\nabla \cdot (V \omega) = V \cdot (\nabla \omega) + \omega (\nabla \cdot V) \approx V \cdot \nabla \omega$$

$$v \int_{\mathcal{R}} \nabla^2 \omega d\mathcal{R} = v \int_{A_0} (\nabla \omega) \cdot n dA$$

$$v \int_{A_0} (\nabla \omega) \cdot n dA = v \int_{\mathcal{R}} \nabla \cdot (\nabla \omega) d\mathcal{R} = v \int_{\mathcal{R}} \nabla^2 \omega d\mathcal{R}$$

Similarly, this convective term  $V \cdot \nabla \omega d\mathcal{R}$  integrated over  $\mathcal{R}$ , this can be written as  $\nabla \cdot (V \omega) d\mathcal{R}$  which is again can be written as area integral  $V \omega \cdot n dA$ .  $A_0$  is the area which is encompassing the volume of interest.

Now, this is a subtle mathematical expression I mean certain operations have gone in like grad if it is operated over  $V$  and  $\omega$ , we can write  $V \cdot \text{grad } \omega$  plus  $\omega \text{ div } V$  into divergence of  $V \omega$  simply expand  $\text{grad } \cdot (V \omega)$ .

Now, if we expand this way for incompressible flows, this part divergence of  $V$  is 0 so, we can drop this so, that means, we get this as  $V \cdot \text{grad } \omega$ . Now,  $V \cdot \text{grad } \omega$

omega it is integrated over space, over volume if this volume integral is converted into area integral, then we can write area encompassing that is  $A_{\text{naught}}$ . So,  $\int_V \omega \cdot n$  is a unit normal vector  $dA$ .

So, in this operation Gauss divergence, this Gauss divergence theorem has been applied and  $A_{\text{naught}}$  is the boundary of  $R$ ,  $n$  is the unit normal vector and  $dA$  is the differential element of  $A_{\text{naught}}$ . Now, so, two terms temporal term and the advective term, we have handled.

Temporal term we have seen, can be written as  $\frac{\partial}{\partial t} \int_R \omega \, dR$  and this second term can be written as  $-\int_{A_{\text{naught}}} \omega \cdot n \, dA$  and the remaining term is the viscous term which is  $\nu \int_R \nabla^2 \omega \, dR$ .

This we can write as  $\nu \int_{A_{\text{naught}}} \nabla \omega \cdot n \, dA$  over the space. How? This is also this quantity  $\nu \int_{A_{\text{naught}}} \nabla \omega \cdot n \, dA$  is basically can be written as volume integral again applying Gauss divergence theorem  $\nu \int_{A_{\text{naught}}} \nabla \omega \cdot n \, dA = \nu \int_R \nabla \cdot \nabla \omega \, dR$  and then, this grad dot grad if those are operated, we will get grad square omega  $dR$  integral over  $R$ .

So, integral over  $R$  grad square omega  $dR$  is basically  $\nu \int_{A_{\text{naught}}} \nabla \omega \cdot n \, dA$ .

(Refer Slide Time: 11:28)

*Conservative property (contd.)*

---

Finally, we can write

$$\frac{\partial}{\partial t} \int_{\mathcal{R}} \omega \, d\mathcal{R} = - \int_{A_0} (V\omega) \cdot n \, dA + \nu \int_{A_0} (\nabla \omega) \cdot n \, dA \quad (2)$$

which implies that the time rate of accumulation of  $\omega$  in  $\mathcal{R}$  is equal to net advective flux rate of  $\omega$  across  $A_0$  into  $\mathcal{R}$  plus net diffusive flux rate of  $\omega$  across  $A_0$  into  $\mathcal{R}$ . The concept of conservative property is to maintain this integral relation in finite difference representation.

Finally, we can write

$$\frac{\partial}{\partial t} \int_{\mathcal{R}} \omega d\mathcal{R} = - \int_{A_0} (V\omega) \cdot n dA + \nu \int_{A_0} (\nabla \omega) \cdot n dA \quad (2)$$

So, all three terms now, we have at our disposal. We can write the integration of vorticity transport equation as  $\frac{\partial}{\partial t} \int_{\mathcal{R}} \omega d\mathcal{R} = - \int_{A_0} (V\omega) \cdot n dA + \nu \int_{A_0} (\nabla \omega) \cdot n dA$

Now, this way when we can write, we can say the time rate of accumulation of omega in R is equal to net advective flux rate of omega across the area that is describing the region R plus net diffusive flux rate of omega again across R that is across area that is describing R.

The concept of conservative property is to remain this integral relation in the finite difference formulation that means, when the formulation will be done, we will be able to appreciate that convective fluxes are through formulation crossing the entire space smoothly and diffusive for flux also crossing the entire definition of space smoothly.

(Refer Slide Time: 13:22)

*Conservative property (contd.)*

Conservative form of Burger's equation

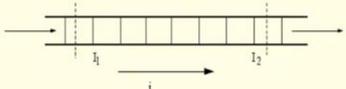

For clarity, again let us consider inviscid Burger's equation. This time we let  $\zeta = \omega =$  vorticity, which means

$$\frac{\partial \omega}{\partial t} = \frac{\partial}{\partial x} (u\omega) \quad (3)$$

The finite difference analog is given by FTCS method as

$$\frac{\omega_i^{n+1} - \omega_i^n}{\Delta t} = \frac{u_{i+1}^n \omega_{i+1}^n - u_{i-1}^n \omega_{i-1}^n}{2\Delta x}$$

Let us consider a region  $\mathcal{R}$  running from  $i = I_1$  to  $i = I_2$  see (Figure). We evaluate the integral  $\frac{1}{\Delta t} \sum_{i=I_1}^{I_2} \omega \Delta x$  as

### Conservative form of Burger's equation

For clarity, again let us consider inviscid Burger's equation. This time we let  $\zeta = \omega =$  vorticity, which means

Let us consider an inviscid Burgers' equation

$$\frac{\partial \omega}{\partial t} = \frac{\partial (u\omega)}{\partial x} \quad (3)$$

$$\frac{\omega_i^{n+1} - \omega_i^n}{\Delta t} = \frac{u_{i+1}^n \omega_{i+1}^n - u_{i-1}^n \omega_{i-1}^n}{2\Delta x}$$

Let us consider a region  $\mathfrak{R}$  running from  $i=I_1$  to  $i=I_2$  see (Figure). We evaluate the integral

$$\frac{1}{\Delta t} \sum_{i=I_1}^{I_2} \omega \Delta x \text{ as}$$

Now, how typically that can be shown or proved. We will take a recourse to again Burger's equation. This is conservative form of Burger equation. As we said that now we are saying conservative form that means, this convective term, this original form has to be convoluted to a conservative form and how that is done? That is done in this way  $\frac{\partial \omega}{\partial t} = \frac{\partial (u\omega)}{\partial x}$ .

And then, if we discretize using FTCS forward time central space, we can write  $\omega$  at  $i$ th point  $n+1$  minus  $\omega$  at  $i$ th point  $n$  divided by  $\Delta t$  equal to so, you are writing expressing this using central difference centered in space  $u_{i+1} \omega_{i+1} - u_{i-1} \omega_{i-1}$  all are at  $n$ th level.

And let us consider a region which is  $R$  one-dimensional volume running from and we are dividing it by number of compartments running from  $i=1$  to  $i=I_2$ . This is  $i$  running through.

So, now, we evaluate this integral which in discretized form if we write it is  $\frac{1}{\Delta t}$  by  $\Delta t$ , then summation of since we are integrating over this summation of  $\omega \Delta x$  over  $i=1$  to  $i=2$ . So, left-hand side becomes this. Then, right-hand side simply will become summation of this entire space. So, summation of this quantity  $\Delta x$  over  $i=1$  to  $i=2$ .

(Refer Slide Time: 15:49)

Conservative property (contd.)

$$\frac{1}{\Delta t} \left[ \sum_{i=I_1}^{I_2} \omega_i^{n+1} \Delta x - \sum_{i=I_1}^{I_2} \omega_i^n \Delta x \right] = \sum_{i=I_1}^{I_2} \frac{(u_{i+1}^n \omega_{i+1}^n) - (u_{i-1}^n \omega_{i-1}^n)}{2\Delta x} = \frac{1}{2} \sum_{i=I_1}^{I_2} [(u\omega)_{i-1}^n - (u\omega)_{i+1}^n] \quad (4)$$

Summation of the right-hand side finally gives

$$\begin{aligned} \frac{1}{\Delta t} \left[ \sum_{i=I_1}^{I_2} \omega_i^{n+1} \Delta x - \sum_{i=I_1}^{I_2} \omega_i^n \Delta x \right] &= \frac{1}{2} [(u\omega)_{I_1-1}^n + (u\omega)_{I_1}^n] \\ &\dots\dots\dots \\ &- \frac{1}{2} [(u\omega)_{I_2}^n + (u\omega)_{I_2+1}^n] \\ &= (u\omega)_{I_1-1/2}^n - (u\omega)_{I_2+1/2}^n \quad (5) \end{aligned}$$

Eq. (5) states that the rate of accumulation of  $\omega_i$  in  $\mathfrak{R}$  is identically equal to the net advective flux rate across the boundary of  $\mathfrak{R}$  running from  $i = I_1$  to  $i = I_2$ . Thus, the FDE analog to inviscid part of the integral Eq. (3) has preserved the conservative property. As such, conservative property depends on the form of the continuum equation.

$$\begin{aligned} \frac{1}{\Delta t} \left[ \sum_{i=I_1}^{i=I_2} \omega_i^{n+1} \Delta x - \sum_{i=I_1}^{i=I_2} \omega_i^n \Delta x \right] &= \sum_{i=I_1}^{i=I_2} \frac{(u_{i+1}^n \omega_{i+1}^n) - (u_{i-1}^n \omega_{i-1}^n)}{2\Delta x} \Delta x \\ &= \frac{1}{2} \sum_{i=I_1}^{i=I_2} [(u\omega)_{i-1}^n - (u\omega)_{i+1}^n] \quad \dots(4) \end{aligned}$$

Summation of the right -hand side finally gives

$$\begin{aligned} \frac{1}{\Delta t} \left[ \sum_{i=I_1}^{i=I_2} \omega_i^{n+1} \Delta x - \sum_{i=I_1}^{i=I_2} \omega_i^n \Delta x \right] &= \frac{1}{2} \sum_{i=I_1}^{i=I_2} [(u\omega)_{i-1}^n - (u\omega)_{i+1}^n] \\ &\dots\dots\dots \\ &- \frac{1}{2} \sum_{i=I_1}^{i=I_2} [(u\omega)_{i_2}^n - (u\omega)_{i_{2+1}}^n] \\ &= (u\omega)_{I_1-1/2}^n - (u\omega)_{I_2+1/2}^n \quad (5) \end{aligned}$$

And exactly we are doing that 1 by delta t omega i n plus 1 delta x minus omega i n delta x i equal to I 1 to I 2, i equal to I 1 to I 2 this is equal to what we did here basically this quantity will be integrated over the space i equal to 1 to i equal to 2 and I have done a small mistake delta x will come here, delta x has come on the left-hand side, delta x will appear on the right-hand side too.

So, it is half  $i$  equal to 1 to  $i$  equal to 2  $u \omega_i$  minus 1  $n$  minus  $u \omega_i$  plus 1  $n$  this minus sign has been absorbed inside and then, we can write this way. So, please you know be careful.

I have done two small mistakes here. I should have written a  $\Delta x$  here and then, as a result of this entire operation, this quantity summation over  $i$  equal to 1 to 2  $\Delta x$  is equal to this half summation of  $i$  equal to 1 to 2  $u \omega_i$  minus 1 minus  $u \omega_i$  plus 1 at  $n$ th level. So, it will run over this control volume, this quantity from  $i$  minus 1 to we will get it up to  $i$  plus 1.

So, left-hand side we are not changing, right-hand side that means, this fluxes if we now vary  $i$ , if we write  $i$  equal to 1, then it is  $I_1$  minus 1 and this will produce  $I_1$ . Next term will be basically we can write  $i$  equal to 2 so, then, it will be  $i$  say  $i$   $I_1$  minus 1 to  $I_1$  plus 1 that means,  $I_1$ . So,  $I_1$  plus to  $I_2$  we will run. So, next term will be  $I_1$  plus 1. So,  $I_1$  plus 1 if we substitute here, that will be  $I_1$  and then, this will be minus quantity  $I_2$ ;  $I_2$ ;  $I_2$ ;  $I_2$   $I_1$  plus 2 at  $n$ th level.

So, we will be able to form an array, just substitute  $i$  equal to first  $I_1$ , then  $i$  equal to  $I_1$  plus 1,  $i$  equal to  $I_1$  plus 2,  $i$  equal to  $I_1$  plus 3 ultimately  $i$  equal to  $I_2$  minus 1  $i$  equal to  $I_2$  we write and then, if you do that simply express these two terms by substituting  $i$  equal to first  $I_1$ , then  $i$  equal to  $I_1$  plus 1, then  $i$  equal to  $I_1$  plus 2 and this way if you go up to  $i$  equal to  $I_2$  minus 1  $i$  equal to  $I_2$  you will get you know array of these two quantities and you will see always you know one term will get cancelled with the another term in the next expression.

And all the terms will be this way intermediate terms will be cancelled out and the final expression which we will get will be basically so, I have given dot dot dot. So, finally,  $i$  equal to  $I_2$  and then, this small  $i$  equal to  $I_2$  so,  $I_2$  and this is  $I_2$  plus 1. So, then you will see that we can, we will be able to write  $u \omega_{I_1}$  minus half minus  $u \omega_{I_2}$  plus half.

So, again let me repeat that we will write  $i$  equal to 1 to  $I_2$ ,  $i$  will vary here and then, first term will be  $I_1$  minus 1  $I_1$ , second term will be again  $I_1$  plus 1 will come here so, it will be  $i$  it will be  $I_1$  plus 1, then  $I_1$  plus 2 will substitute small  $i$   $I_1$  plus 2 will come here. So, we will get the expressions and the expressions can be arranged in such a way

that all intermediate terms will get cancelled and finally, we will be able to write from here  $u \omega$  at  $I_1 - \frac{1}{2}$  at  $n$ th level minus  $u \omega$  at  $I_2 + \frac{1}{2}$  at  $n$ th level.

So, basically these two last terms, this is the last term, this will constitute this, and this is a first term, this will constitute this. Basically,  $u \omega$  we have written at  $I_1$  and  $I_1 - \frac{1}{2}$  average of that, that means, whatever is entering through this dotted line and finally,  $u \omega$  at  $I_2$  and  $u \omega$  at  $I_2 + \frac{1}{2}$  so, by 2 and this is basically whatever is crossing through this dotted line, we will get that. So, whatever is entering that is going out.

So, equation 5 states that the rate of accumulation of  $\omega$  in  $\mathcal{R}$  is identically equal to the net advective flux rate across the boundary of  $\mathcal{R}$  running from  $i = I_1$  to  $i = I_2$ . Thus, the FDE analog, finite difference analogue to inviscid part of integral equation 3, Burger's equation has preserved the conservative property.

So, you can see if this way we write all intermediate fluxes will get cancelled and whatever is coming in that will be going out, final expression will be this. So, by formulation we are preserving the conservative property.

(Refer Slide Time: 24:16)

*Conservative property (contd.)*

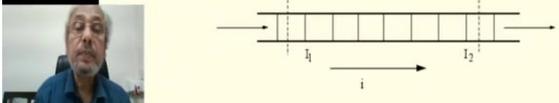

Let us take non-conservative form of inviscid Burger's equation as

$$\frac{\partial \omega}{\partial t} = -u \frac{\partial \omega}{\partial x} \quad (6)$$

Using FTCS differencing technique as before, we can write

$$\frac{\omega_i^{n+1} - \omega_i^n}{\Delta t} = -u_i^n \left[ \frac{\omega_{i+1}^n - \omega_{i-1}^n}{2\Delta x} \right] \quad (7)$$

Now, the integration over  $\mathcal{R}$  running from  $i = I_1$  to  $i = I_2$ , yields

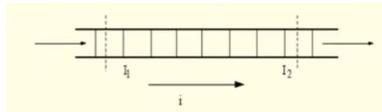

Consider a non-conservative form of inviscid Burger's equation as

$$\frac{\partial \omega}{\partial t} = u \frac{\partial (\omega)}{\partial x} \quad (6)$$

Using FTCS differencing technique as before, we can write

$$\frac{\omega_i^{n+1} - \omega_i^n}{\Delta t} = u_i^n \left[ \frac{\omega_{i+1}^n - \omega_{i-1}^n}{2\Delta x} \right] \quad (7)$$

Now the integration over  $\mathfrak{R}$  running from  $i=I_1$  to  $i=I_2$ , yields

But non-conservative form, if we write minus  $u \text{ del } \omega \text{ del } x$ , then and then integrate it, we will differentiate it first ah, we will get  $\omega_i$  at  $n+1$   $\omega_i$  at  $n$  divided by  $\Delta t$  equal to minus  $u$  at  $n$ th level here  $\omega_{i+1} - \omega_{i-1}$  centered in space at  $n$ th level divided by twice  $\Delta x$  and again we will run  $i$  equal to  $I_1$  to  $I_2$ .

(Refer Slide Time: 24:55)

*Conservative property (contd.)*

$$\frac{1}{\Delta t} \left[ \sum_{i=I_1}^{I_2} \omega_i^{n+1} \Delta x - \sum_{i=I_1}^{i=I_2} \omega_i^n \Delta x \right] = \sum_{i=I_1}^{i=I_2} -u_i^n \frac{(\omega_{i+1}^n - \omega_{i-1}^n)}{2\Delta x}$$

$$= \frac{1}{2} \sum_{i=I_1}^{i=I_2} [u_i^n \omega_{i-1}^n - u_i^n \omega_{i+1}^n]$$

While performing the summation of the right-hand side of Eq. (7), it can be observed that terms corresponding to inner cell fluxes do not cancel out. Consequently, an expression in terms of fluxes at the inlet and outlet section, as it was found earlier, could not be obtained. Hence the finite-difference analog Eq. (7) has failed to preserve the integral Gauss-divergence property, i.e. the conservative property of the continuum.

$$\frac{1}{\Delta t} \left[ \sum_{i=I_1}^{i=I_2} \omega_i^{n+1} \Delta x - \sum_{i=I_1}^{i=I_2} \omega_i^n \Delta x \right] = \sum_{i=I_1}^{i=I_2} -u_i^n \frac{(\omega_{i+1}^n - \omega_{i-1}^n)}{2\Delta x}$$

$$= \frac{1}{2} \sum_{i=I_1}^{i=I_2} \frac{(u_i^n \omega_{i-1}^n - u_i^n \omega_{i+1}^n)}{2}$$

Then, if we write down the expressions of this integral, here also we have to write  $\Delta x$  here, I have miss that please be careful, I will try to represent these two slides in my next lecture again so that you can correct that. So, and then, you express in this way.

But in this way, now, if you substitute  $i$  equal to  $I_1$  and then  $i$  equal to  $I_1 + 1$ ,  $i$  equal to  $I_1 + 2$  up to  $I_2$ , you will see you form the array taking two-three terms that means,  $i$  equal to 1,  $i$  equal to 1  $i$  equal to  $I_1$ ,  $i$  equal to  $I_1 + 1$ ,  $i$  equal to  $I_1 + 2$  and then, last three terms may be  $i$  equal to  $I_2 - 1$ ,  $i$  equal to  $I_2$ . You will see all intermediate terms are you know not cancelling at all.

So, basically fluxes are by definition not eventually balanced. So, while performing the summation of the right-hand side of you have written equation 7, it can be observed that terms corresponding to inner cell fluxes do not cancel out.

Consequently, an expression in terms of fluxes at inlet and outlet section, as it was found earlier, could not be obtained. Hence finite difference analog of 7 has failed to preserve the integral Gauss divergence property that is conservative property of the continuum.

So, again little repetition. This is conservative formulation and conservative formulation final expression of left-hand side is equal to this I I said that I am missed equal to sign in front of this expression. Here, if you keep on  $i$  equal to keep on substituting  $i$  equal to  $I_1$ , then  $I_1 + 1$ ,  $I_1 + 2$  may be three terms and then,  $i$  equal to  $I_2 - 1$ ,  $i$  equal to  $I_2 + 2$  or 3 terms, you will see fluxes can be arranged such a way that all intermediate fluxes will get cancelled. The in the domain, the inlet flux will just go out as out let out flux, in flux will just go out as out flux.

So, basically it will by formulation itself or by writing itself in this way conservative form, we are retaining conservative property whereas, by writing this way which is equation 6, we are not retaining conservative property non-conservative form.

(Refer Slide Time: 28:25)

*Conservative property (contd.)*

The meaning of calling Eq. (3) as “conservative form” is now clearly understood. However, the conservative form of advective part is of prime importance for modeling fluid flow and is often referred to as weak conservative form. For the incompressible flow in Cartesian coordinate this form is:

$$\frac{\partial u}{\partial t} + \frac{\partial u^2}{\partial x} + \frac{\partial uv}{\partial y} + \frac{\partial uw}{\partial z} = -\frac{1}{\rho} \frac{\partial p}{\partial x} + \nu \nabla^2 u$$

$$\frac{\partial v}{\partial t} + \frac{\partial uv}{\partial x} + \frac{\partial v^2}{\partial y} + \frac{\partial vw}{\partial z} = -\frac{1}{\rho} \frac{\partial p}{\partial y} + \nu \nabla^2 v$$

$$\frac{\partial w}{\partial t} + \frac{\partial uw}{\partial x} + \frac{\partial vw}{\partial y} + \frac{\partial w^2}{\partial z} = -\frac{1}{\rho} \frac{\partial p}{\partial z} + \nu \nabla^2 w$$

For the incompressible flow in Cartesian coordinate the conservative form is:

$$\frac{\partial u}{\partial t} + \frac{\partial u^2}{\partial x} + \frac{\partial uv}{\partial y} + \frac{\partial uw}{\partial z} = -\frac{1}{\rho} \frac{\partial p}{\partial x} + \nu \Delta^2 u$$

$$\frac{\partial v}{\partial t} + \frac{\partial uv}{\partial x} + \frac{\partial v^2}{\partial y} + \frac{\partial vw}{\partial z} = -\frac{1}{\rho} \frac{\partial p}{\partial y} + \nu \Delta^2 v$$

$$\frac{\partial w}{\partial t} + \frac{\partial uw}{\partial x} + \frac{\partial vw}{\partial y} + \frac{\partial w^2}{\partial z} = -\frac{1}{\rho} \frac{\partial p}{\partial z} + \nu \Delta^2 w$$

So, from here that means, the calling equation 3 as conservative is now clearly understood. However, the conservative form of advective part is of prime importance for modeling fluid flow and is often referred to as weak conservative form. So, instead of writing  $\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z} = -\frac{1}{\rho} \frac{\partial p}{\partial x} + \nu \nabla^2 u$  we can write it in this way  $\frac{\partial}{\partial t} \left( \frac{\rho u}{\rho} \right) + \frac{\partial}{\partial x} \left( \frac{\rho u^2}{\rho} \right) + \frac{\partial}{\partial y} \left( \frac{\rho uv}{\rho} \right) + \frac{\partial}{\partial z} \left( \frac{\rho uw}{\rho} \right) = -\frac{1}{\rho} \frac{\partial p}{\partial x} + \nu \Delta^2 u$ .

Similarly, y momentum equation our non-conservative form is  $\frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} + w \frac{\partial v}{\partial z} = -\frac{1}{\rho} \frac{\partial p}{\partial y} + \nu \nabla^2 v$  instead of that we will write  $\frac{\partial}{\partial t} \left( \frac{\rho v}{\rho} \right) + \frac{\partial}{\partial x} \left( \frac{\rho uv}{\rho} \right) + \frac{\partial}{\partial y} \left( \frac{\rho v^2}{\rho} \right) + \frac{\partial}{\partial z} \left( \frac{\rho vw}{\rho} \right) = -\frac{1}{\rho} \frac{\partial p}{\partial y} + \nu \Delta^2 v$  right-hand side, we are not touching. So, all the advective terms, the convective terms can be written in conservative form. Now, if

we only write the advective terms or advection in conservative form, then that is called weak conservation.

(Refer Slide Time: 30:21)

*Conservative property (contd.)*

If all the terms in the flow equation are recast in the form of first-order derivative of  $x, y, z$  and  $t$ , the equations are said to be in strong "conservative form". We shall write the strong conservation form of Navier-Stokes equations in Cartesian coordinate system:

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} \left( u^2 + \frac{p}{\rho} - \nu \frac{\partial u}{\partial x} \right) + \frac{\partial}{\partial y} \left( uv - \nu \frac{\partial u}{\partial y} \right) + \frac{\partial}{\partial z} \left( uw - \nu \frac{\partial u}{\partial z} \right) = 0$$

$$\frac{\partial v}{\partial t} + \frac{\partial}{\partial x} \left( uv - \nu \frac{\partial u}{\partial x} \right) + \frac{\partial}{\partial y} \left( v^2 + \frac{p}{\rho} - \nu \frac{\partial v}{\partial y} \right) + \frac{\partial}{\partial z} \left( wv - \nu \frac{\partial v}{\partial z} \right) = 0$$

$$\frac{\partial w}{\partial t} + \frac{\partial}{\partial x} \left( uw - \nu \frac{\partial w}{\partial x} \right) + \frac{\partial}{\partial y} \left( vw - \nu \frac{\partial w}{\partial y} \right) + \frac{\partial}{\partial z} \left( w^2 + \frac{p}{\rho} - \nu \frac{\partial w}{\partial z} \right) = 0$$

The strong conservation form of Navier-Stokes equations in Cartesian coordinate system:

$$\frac{\partial u}{\partial t} + \frac{\partial}{\partial x} \left( u^2 + \frac{p}{\rho} - \nu \frac{\partial u}{\partial x} \right) + \frac{\partial}{\partial y} \left( uv - \nu \frac{\partial u}{\partial y} \right) + \frac{\partial}{\partial z} \left( uw - \nu \frac{\partial u}{\partial z} \right) = 0$$

$$\frac{\partial v}{\partial t} + \frac{\partial}{\partial x} \left( uv - \nu \frac{\partial u}{\partial x} \right) + \frac{\partial}{\partial y} \left( v^2 + \frac{p}{\rho} - \nu \frac{\partial v}{\partial y} \right) + \frac{\partial}{\partial z} \left( wv - \nu \frac{\partial v}{\partial z} \right) = 0$$

$$\frac{\partial w}{\partial t} + \frac{\partial}{\partial x} \left( uw - \nu \frac{\partial w}{\partial x} \right) + \frac{\partial}{\partial y} \left( vw - \nu \frac{\partial w}{\partial y} \right) + \frac{\partial}{\partial z} \left( w^2 + \frac{p}{\rho} - \nu \frac{\partial w}{\partial z} \right) = 0$$

In a similar manner, if we try to write all the terms as first order derivative of  $x, y$  and  $z$  and  $t$ , then we will be able to get something which is called strong conservative form. You have seen that what we have done now. Now, right-hand side also enters into the expression in terms of wherever it fits in  $\text{del del } xy$  or  $\text{del del } x$  or  $\text{del del } y$  or  $\text{del del } z$ .

You can see  $\text{del } u \text{ del } t$  plus  $\text{del del } x$  of  $u^2$  plus  $p$  by  $\rho$  minus  $\nu \text{ del } u \text{ del } x$ . If you move into the right-hand side, it will be  $\text{del del } x$  minus  $1$  by  $\rho \text{ del } p \text{ del } x$  that has

been brought here and if you again shift this to right-hand side, this will be  $\nu \frac{\partial^2 u}{\partial x^2}$  that has come here.

So, similarly  $\frac{\partial}{\partial x} (uv)$  and right-hand side from Laplacian  $u$ , if you bring  $2u \frac{\partial u}{\partial x}$  on this side, you will be able to get this and if you bring  $\nu \frac{\partial^2 u}{\partial x^2}$  on left side, you will get left-hand side, you will get this. Similar way  $v$  momentum equation or  $y$  momentum equation can be written, or the  $z$  momentum equation can be written. When you write in this way, it is called conservative form, strong conservative form.

Strong conservative form is not a mandatory requirement because of ease of formulation at times strong conservative form is preferred. In quite a few well-known algorithms, the equations are discretized in non in strong conservative form. This way in strong conservative form, but as I mentioned earlier, weak conservative form that means, writing convective derivatives or advection terms in conservative form is often very very helpful and in almost all the well-known algorithms, it is done this way.

So, we have learned first conservative form of convective term, it always balances convective flux by through its definition. Second is this conservative form of equation can be again written in two different ways; weak conservative form and strong conservative form.

(Refer Slide Time: 33:49)

### Upwind Scheme

Once again, we shall start with the inviscid Burger's equation. Regarding discretization, we can think about the following formulations

$$\frac{z_i^{n+1} - z_i^n}{\Delta t} + u \frac{z_{i+1}^n - z_i^n}{\Delta x} = 0 \quad (1)$$

$$\frac{z_i^{n+1} - z_i^n}{\Delta t} + u \frac{z_{i+1}^n - z_{i-1}^n}{2\Delta x} = 0 \quad (2)$$

If Von Neumann's stability analysis is applied to these schemes, we find that both are unconditionally unstable.

A well-known remedy for the difficulties encountered in such formulations is the upwind scheme which is described by Gentry, Martin and Daly (1966) and Runchal and Wolfshtein (1969). Eq. (1) can be made stable by substituting the forward space difference by a backward space difference scheme, provided that the carrier velocity  $u$  is positive. If  $u$  is negative, a forward difference scheme must be used to assure stability. For full Burger's equation, the formulation of the diffusion term remains unchanged and only the convective term (in conservative form) is calculated in a special way

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} + u \left[ \frac{\zeta_{i+1}^n - \zeta_i^n}{\Delta x} \right] = 0 \quad (1)$$

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} + u \left[ \frac{\zeta_{i+1}^n - \zeta_{i-1}^n}{2\Delta x} \right] = 0 \quad (2)$$

Now, again I will go back to Burger's equation in terms of zeta. So, del zeta del t plus u del zeta del x and now, we will write two different finite difference schemes. One is you can very well appreciate equation 1 forward in time and a non-conservative form also forward in space not centered in space, but forward in space.

Second one, again forward in time zeta n plus i at ith location n plus 1 minus zeta at ith location n divided by delta t plus u zeta i plus 1 at n minus zeta i minus 1 at n divided by twice delta x. Now, this is called again non conservative form central difference.

Now, if you apply Von Neumann stability analysis which we learned earlier that formulation is stable or not from numerical stability point of view, although we do not have this custom here, but if we try to perform for Neumann stability analysis, we will find both this formulation 1 and 2 are unconditionally unstable that means, whatever you do, it will blow off, the calculation will not converge.

So, obviously, you know we have to look for the reason and look for the remedy. I have given name of few scientist; one is Gentry, Martin and Daly again, this group is from Los Alamos and Runchal and Wolfshtein again both of them were at that time at Imperial college. Although Runchal is an Indian, many of you might be knowing him.

He was at Imperial College. Wolfshtein, he is from Israel basically very well-known two students of Professor Spalding and their this we are co-workers of Professor Harlow at Los Alamos anyway. To cut the long story short that they experimented in those days people were trying to evolve Navier-Stokes solver and you know several other experiments with full Navier-Stokes equations. So, these were very relevant and very important.

Now, they found out that the very efficient way to get you know such derivatives stabilized is the following that is we have written equation 1 can be made stable by substituting the forward space difference by a backward space difference scheme,

provided the carrier velocity is positive means if u is positive and then instead of forward difference scheme, if we write backward difference scheme or rearward difference scheme, if this will be stable.

If u is negative, then if u is a negative velocity, then forward difference scheme must be used to assure stability. For full Burger's equation, the formulation of the diffusion term remains unchanged and only the convective terms will matter. So, what we will do?

We only consider convective term, number 1 and number 2 we have already sort of tested that conservative form is more effective or more useful. So, we will apply this philosophy, that means, if u is positive, go by rearward difference, backward difference. If u is negative, go by forward difference of the dependent flow variable.

(Refer Slide Time: 39:25)

*Upwind Scheme*

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_i^n - u \zeta_{i-1}^n}{\Delta x} + \text{viscous term, for } u > 0 \quad (3)$$

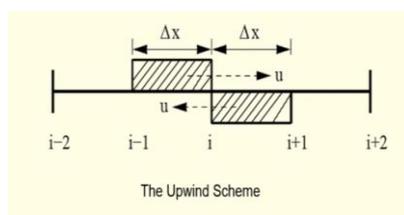

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_{i+1}^n - u \zeta_i^n}{\Delta x} + \text{viscous term, for } u < 0 \quad (4)$$

It is also well known that upwind method of discretization is very much necessary in convection (advection) dominated flows in order to obtain numerically stable results. As such, upwind bias retains transportative property of flow equation. Let us have a closer look at the transportative property and related upwind bias.

The Upwind Scheme

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_i^n - u \zeta_{i-1}^n}{\Delta x} + \text{viscous term, for } u > 0 \quad (3)$$

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_{i+1}^n - u \zeta_i^n}{\Delta x} + \text{viscous term, for } u < 0 \quad (4)$$

Now, we have exactly done that  $\zeta_i^{n+1} - \zeta_i^n$  at nth level by  $\Delta t$  equal to  $-\zeta_i^n u_i^n$  conservative form  $u_i^n \zeta_{i-1}^n$  plus viscous term for  $u$  greater than 0 and  $-\zeta_{i+1}^n - u_i^n \zeta_i^n$  for  $u$  less than 0, that means, for  $u$  negative and this is  $i - i - 1$  for  $u$  positive,  $\zeta_{i+1}^n - \zeta_{i-1}^n$  for  $u$  positive and  $-\zeta_{i+1}^n - \zeta_{i-1}^n$  for  $u$  negative and since, conservative formulation  $u$  and  $\zeta$  are together.

It is also well-known that upwind method of discretization is very much necessary in convection dominated flows. It is basically what is meant is high speed flows and I will discuss later that this is this was a major bottleneck for solving full Navier-Stokes equations for higher Reynolds number and this was specifically a problem with finite element formulation.

Anyway, we will not confuse with those information now, what we will do that we will take it up equation 3 and equation 4 and we will test its effect on again a one-dimensional domain running from  $i - 2$ ,  $i - 1$ ,  $i$ ,  $i + 1$ ,  $i + 2$  and once we will take  $u$  as positive so, in the positive direction and in their occasion, we will take  $u$  as negative,  $u$  running in the negative direction, that means, in the opposite direction of the coordinate system.

(Refer Slide Time: 41:59)

*Transportive Property*

Consider the model Burger's equation in conservative form (5)

$$\frac{\partial \zeta}{\partial t} = -\frac{\partial u \zeta}{\partial x}$$

Let us examine a method which is central in space. Using FTCS we get

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u_{i+1}^n \zeta_{i+1}^n - u_{i-1}^n \zeta_{i-1}^n}{2\Delta x} \quad (6)$$

$$\frac{\partial \zeta}{\partial t} = -\frac{\partial u \zeta}{\partial x}$$

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u\zeta_{i+1}^n - u\zeta_{i-1}^n}{2\Delta x} \quad (6)$$

So, consider again model Burger equation as I said. So, it and only we will consider temporal term and the convective term del zeta del t equal to minus del del x of u zeta and if we go for FTCS so, u and zeta, u I am not writing specifically i plus 1 it is understood that u is with zeta whatever is the zetas coordinate, u is with it.

So, zeta i plus 1 minus u i zeta i minus 1 by twice delta x this is we know forward time central space otherwise you know consistent good formulation.

(Refer Slide Time: 42:50)

*Transportive Property*

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u\zeta_{i+1}^n - u\zeta_{i-1}^n}{2\Delta x}$$

Consider a perturbation  $\epsilon_m = \delta$  in  $\zeta$ . A perturbation will spread in all directions due to diffusion. We are taking an inviscid model equation and we want the perturbation to be carried along only in the direction of the velocity. So, for  $u > 0$ ,  $\epsilon_m = \delta$  (perturbation at  $m^{\text{th}}$  space location), all other  $\epsilon = 0$ . Therefore, at a point  $(m+1)$  downstream of the perturbation

$$\frac{\zeta_{m+1}^{n+1} - \zeta_{m+1}^n}{\Delta t} = -\frac{0 - u\delta}{2\Delta x} = +\frac{u\delta}{2\Delta x}$$

which is acceptable. However, at the point of perturbation ( $i = m$ ),

$$\frac{\zeta_m^{n+1} - \zeta_m^n}{\Delta t} = -\frac{0 - 0}{2\Delta x} = 0$$

which is not very reasonable.

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u\zeta_{i+1}^n - u\zeta_{i-1}^n}{2\Delta x}$$

$$\frac{\zeta_{m+1}^{n+1} - \zeta_{m+1}^n}{\Delta t} = -\frac{0 - u\delta}{2\Delta x} = +\frac{u\delta}{2\Delta x}$$

$$\frac{\zeta_m^{n+1} - \zeta_m^n}{\Delta t} = -\frac{0 - 0}{2\Delta x} = 0$$

So, we have rewritten that because we will very soon do the analysis on this template, on this equations, on this equation with this terms. Consider a perturbation epsilon m equal

to  $\delta$  in  $\zeta$ . A perturbation will spread in all directions due to diffusion. This is a very nice concept and very natural concept.

If you take a you know for example, steel plate and place a small heated object at the center of it, you will see slowly you know entire plate in all direction equally it will be heated up, temperature will increase or if you throw a stone in a steel water in a small pond so that, you can observe you will see ripples are going with the same speed on all directions and this is very natural way of describing diffusion. So, if we give a perturbation, diffusion will propagate on all direction.

So, since we are taken in an inviscid model so, a perturbation going on all direction that part is eliminated as if it is not diffusing. So, you have switched off the diffusion term and perturbation to be carried along, then only in the direction of velocity it will go. So, it is like coloring a spot in a flow stream. So, if flow stream is not very gently going in one direction, that color will keep spreading in other direction.

So, for  $u > 0$  and this  $\epsilon_m$  equal to  $\delta$  perturbation a perturbation at  $m$ th space location, all other  $\epsilon$ s are 0. Now, if we substitute here having perturbed it at  $m$ th location  $i$  equal to  $m$ , we are trying to see what happens when  $i$  at the next time step at  $i$  equal to  $m + 1$ . So, here we will simply substitute  $i$  by  $m + 1$ .

So, this will be  $\zeta_{m+1, n}$  at  $n + 1$ th level minus  $\zeta_{m+1, n}$  at  $n$ th level by  $\Delta t$  equal to  $-\frac{u}{\Delta x}$  if we substitute  $i$  by  $m + 1$ , it is  $\zeta_{m+2, n}$ .

So, nothing is there if you perturb at  $m$ ;  $m$ th level not the next point, but next to next point and also at  $i - 1$ , that means,  $m - 1$  if we substitute here that means, at  $m$ th point,  $m$ th point we have disturbed,  $\delta$  is there at  $m$ th point.

So, we are we can see this is plus it is becoming twice  $\delta$  by  $u \Delta t$  by twice  $\Delta x$  which is acceptable right because at the next point, you will find at  $m + 1$ th  $m + 1$ ;  $1$ th point in the space you will get some effect of perturbation giving perturbation at  $m$ th point that is why we have written which is acceptable.

However, at the point of perturbation what is happening? If we substitute  $i$  by  $m$  here also if we substitute  $i$  so, this will be  $\zeta_{m, n+1}$  minus  $\zeta_{m, n}$  divided by

delta t equal to here i is substituted by m. So, at m plus 1 and m minus 1. Now, perturbation is not there at m minus 1 or m plus 1.

Here at mth point earlier case, perturbation we substituted by perturbation, but here at m plus 1th point, no perturbation, m minus 1th point no perturbation 0 which is not very reasonable because after giving perturbation, the next time step itself you are not able to fill anything there you know no quantity there is not very reasonable.

(Refer Slide Time: 48:38)

*Transportive Property*

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_{i+1}^n - u \zeta_{i-1}^n}{2\Delta x}$$

But at the upstream station ( $i = m - 1$ ) we observe

$$\frac{\zeta_{m-1}^{n+1} - \zeta_{m-1}^n}{\Delta t} = \frac{u\delta - 0}{2\Delta x} = \frac{u\delta}{2\Delta x}$$

which indicates that the transportive property is violated.  
On the contrary, let us see what happens when an upwind scheme is used.  
We know that for  $u > 0$

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_i^n - u \zeta_{i-1}^n}{\Delta x} \quad (7)$$

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_{i+1}^n - u \zeta_{i-1}^n}{2\Delta x}$$

But at the upstream location ( $i = m - 1$ ) we observe

$$\frac{\zeta_{m-1}^{n+1} - \zeta_{m-1}^n}{\Delta t} = \frac{u\delta - 0}{2\Delta x} = \frac{u\delta}{2\Delta x}$$

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_i^n - u \zeta_{i-1}^n}{\Delta x} \quad (7)$$

Again, I have written in the same form of equation. At m minus 1th point so, again you know i is; i is substituted by m minus 1 and this is u zeta and u this u zeta, i should be substituted by m minus 1. So, m minus 1 means this is m and m minus 1 means this is m

minus 2. So, at m minus 2 point, nothing is there. At if we give m minus 1, this is mth point. So, mth point delta perturbation.

So, we can see this is becoming equal to minus u delta by twice x which indicates that at m, but finally, we are observing at m minus 1th level m minus 1th point sorry at the point m minus 1 special point.

Now, u velocity is in the positive direction. So, i, i plus 1, i plus 2 all are points in the positive direction, u velocity is moving in the positive direction. After giving a perturbation, if we get effect of the perturbation in the i minus at i minus 1 point or at i minus 2 point which are in fluid mechanical language upstream points.

So, when u is positive, upstream point should not get perturbed, but we can see upstream point is getting perturbed. So, this is not really acceptable, we can say transportive property is violated.

Now, so, but it was FTCS formulation, right, equation 6 is FTCS formulation. So, again conservative form of equation that means, equation 5 we will go for the formulation for u positive. Now, what we said if u is positive, then it will be backward difference.

So, for positive u, we have to involve a point which is at the behind which is basically upstream point. So, u zeta i n minus u zeta i minus 1 n by delta x for u greater than 0. So, for positive u, we involve the upstream point or the backward difference.

(Refer Slide Time: 52:05)

*Transportive Property*

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_i^n - u \zeta_{i-1}^n}{\Delta x}$$

Then for  $\epsilon_m = \delta$  at the downstream location  $(m + 1)$

$$\frac{\zeta_{m+1}^{n+1} - \zeta_{m+1}^n}{\Delta t} = -\frac{0 - u \delta}{\Delta x} = +\frac{u \delta}{\Delta x}$$

which follows the rationale for the transport property.  
At point  $m$  of the disturbance

$$\frac{\zeta_m^{n+1} - \zeta_m^n}{\Delta t} = -\frac{u \delta - 0}{\Delta x} = -\frac{u \delta}{\Delta x}$$

which means that the perturbation is being transported out of the affected region.

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u\zeta_i^n - u\zeta_{i-1}^n}{\Delta x}$$

Then for  $\varepsilon_m = \delta$  at the downstream location  $(m+1)$

$$\frac{\zeta_{m+1}^{n+1} - \zeta_{m+1}^n}{\Delta t} = -\frac{0 - u\delta}{\Delta x} = +\frac{u\delta}{\Delta x}$$

which follows the rationale for the transport property.

At point  $m$  of the disturbance

$$\varepsilon_m = \delta \frac{\zeta_m^{n+1} - \zeta_m^n}{\Delta t} = -\frac{u\delta - 0}{\Delta x} = -\frac{u\delta}{\Delta x}$$

So, then, we can write this form that means, we know now that  $u$  is positive so, that difference is  $i$  minus  $u$   $u$   $\zeta_i$  minus  $u$   $\zeta_{i-1}$ . Again, we are perturbing at  $m$ th location and then, we can we will see what is happening to  $m+1$ . So, we substitute  $i$  by  $m+1$  and this is at  $m+1$ , we did not give any perturbation at  $m+1$  so, we will write  $0$  perturbation value is  $0$ , but if  $m+1$  is substituted to this  $I$ , this is  $m$ , perturbation value was given there.

So, this quantity is at the next time level at the next point is becoming  $u\delta$  by  $\Delta x$  which follows the rational for the transportive property that means, in the forward point, it must move. At point  $m$  of the disturbance, again in this equation you substitute all is by  $m$ 's so, we have done that.

Now, since at  $m$ th point disturbance was given, but  $m-1$  point there was no disturbance so, we can see at  $m$ th point at the next time level what is happening? You know some effect of perturbation we are able to see that means, a perturbation is you know being transported out, it has a negative sign also.

(Refer Slide Time: 53:55)

*Transportive Property*

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_i^n - u \zeta_{i-1}^n}{\Delta x}$$

Finally, at  $(m-1)$  station, we observe that

$$\frac{\zeta_{m-1}^{n+1} - \zeta_{m-1}^n}{\Delta t} = -\frac{0-0}{\Delta x} = 0$$

This signifies that no perturbation effect is carried upstream. In other words, the upwind method maintains unidirectional flow of information. In conclusion, it can be said that while space centered difference are more accurate than upwind differences, as indicated by the Taylor series expansion, the whole system is not more accurate if the criteria for accuracy includes the transportive property as well

$$\frac{\zeta_i^{n+1} - \zeta_i^n}{\Delta t} = -\frac{u \zeta_i^n - u \zeta_{i-1}^n}{\Delta x}$$

Finally, at  $(m-1)$  station, we observe that

$$\frac{\zeta_{m-1}^{n+1} - \zeta_{m-1}^n}{\Delta t} = -\frac{0-0}{\Delta x} = 0$$

Again, you know if we observed at  $m$  minus 1 station, we have repeatedly written this equation so that we can easily substitute  $m$  minus 1 and if it is  $m$  minus 1, there is no perturbation at  $m$  minus 1. If we substitute  $i$  by  $m$  minus 1, then it is  $u \zeta_{m-2}^n$  there is no perturbation there, so these are 0 equal to 0. So, at the upstream point that means, a point behind there is no effect.

So, this signifies that no perturbation effect is carried upstream. In other words, upwind method maintains unidirectional flow information. In conclusion, it can be said that while space centered difference are more accurate, space centered difference schemes they are more accurate than upwind differences, as indicated by Taylor series expansion that we have seen earlier in our first few lectures.

The whole system is not more accurate if the criteria for accuracy includes transportive property because here, there is a bias, the fluid velocity is inducing that bias on the space. So, this is not a stagnant space, we are not solving heat conduction problem. Here, the

medium is moving, and flow velocity is affecting. So, the finite difference portion will be very appropriate if this effect is inducted, if this effect is mimicked in formulation and that is what is done if we do or introduce up winding.

Up winding means; again we will go back by the definition given by Gentry, Martin and Daly and Runchal and Wolfshtein that you know you go for first order a difference quotient specially  $\frac{\Delta u}{\Delta x} = \frac{\Delta v}{\Delta x}$  such quantities, you discretize it using backward difference in that means, using upstream point, point which is behind if the flow velocity is positive. If the flow velocity is negative, then you involve downstream point that means forward point.

So, go for forward differencing for locally negative velocity. Go for backward differencing for positive velocity. This philosophy is called up winding and we will see that when we will formulate a complete problem, this information or this guideline helps us a lot although things may not be the so much straight forward.

But the hidden idea will remain the same effectively, we will involve upstream points for positive velocity and downstream points for the negative velocity which we will see be very stable and also will be very accurate, but to maintain the accuracy, we have to involve some additional technique, additional care.

We will do in the subsequent classes. We will stop here today. Thank you very much. This was the conclusion that we will in transportive property is one-directional flow property maintaining that we have to go for up winding. So, we have progressed up to this. We will take up from here in the next class.

Thank you very much.
