

Machinery Fault Diagnosis and Signal Processing
Prof. A. R. Mohanty
Department of Mechanical Engineering
Indian Institute of Technology, Kharagpur

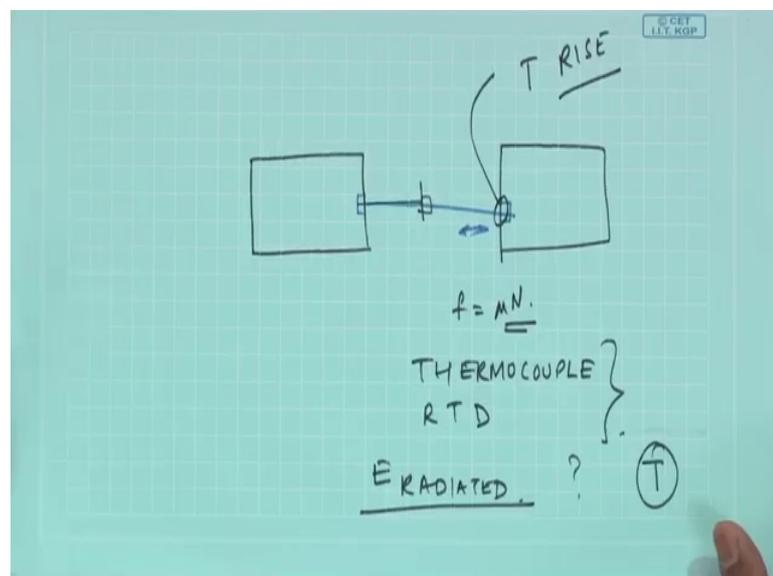

Lecture - 48
Thermography

In this lecture, we always talk about a new area all together and that is known as thermography. By now, we have a knowledge of how vibration can be used for machinery health monitoring or condition monitoring and then in the previous classes, you saw how motor current signature analysis can be used to find out faults in mechanical systems being driven by electrical machines and also find out the faults in the electrical machines themselves.

But today, we will discuss on a new topic called thermography, essentially by the measure of thermal energy emitted from a body as you know, any machine, it generates heat because of friction between the moving parts sliding over one another, there will be lot of heat generation and this heat generation increases with the frictional force and frictional force will increase the normal forces onto the surfaces increase. Now this normal force could increase because of a defect.

So, thermal imaging gives us easy clue as to that an abnormal excessive force is coming on to this machine particularly, for example, I will just give you an example here.

(Refer Slide Time: 01:46)

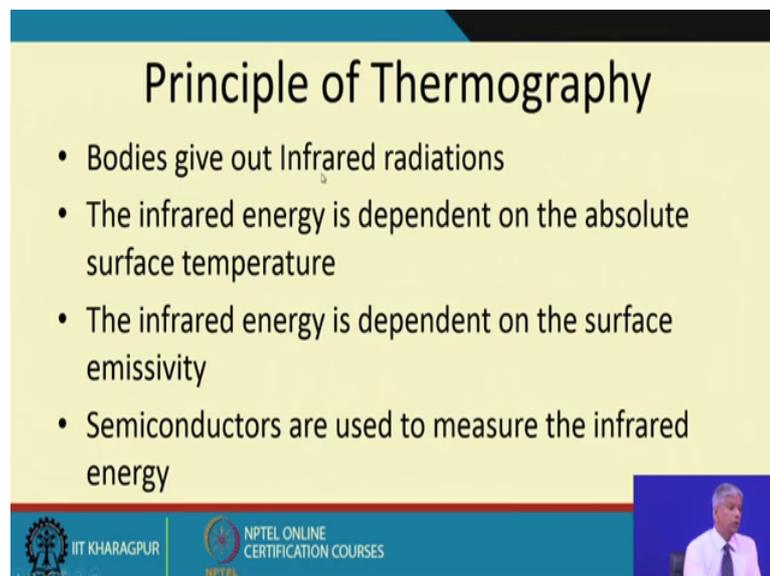

I have two machines and then there is a strong bit of misalignment between these two shafts. So, there will be a push pull force onto the surface of these bearings. So, what happens; the frictional force whatever be the direction ok, it is normal to the direction of the normal force.

Now, if this friction force increases and there will be lot of heat generation ok, if heat generation is there; obviously, the temperature is going to rise. So, indirectly by measuring the rise in temperature, we can say that an abnormal force has happened, well, how can we measure temperature, we know to use thermocouple, to use an resistance temperature detector; RTD, etcetera, we can measure the temperature of any surface, but mind you, these are contacting surfaces, I mean these are contact type sensors. So, we have to embed these sensors in the area where we are going to measure the temperature.

Rather there is another method by which we can measure the temperature is you know because the energy will be radiated thermal energy will be radiated. So, if we can somehow measure this radiated energy, we can get a clue as to; what is the surface temperature and that is essentially, what we are going to talk about in today's lecture on thermography.

(Refer Slide Time: 03:41)

Principle of Thermography

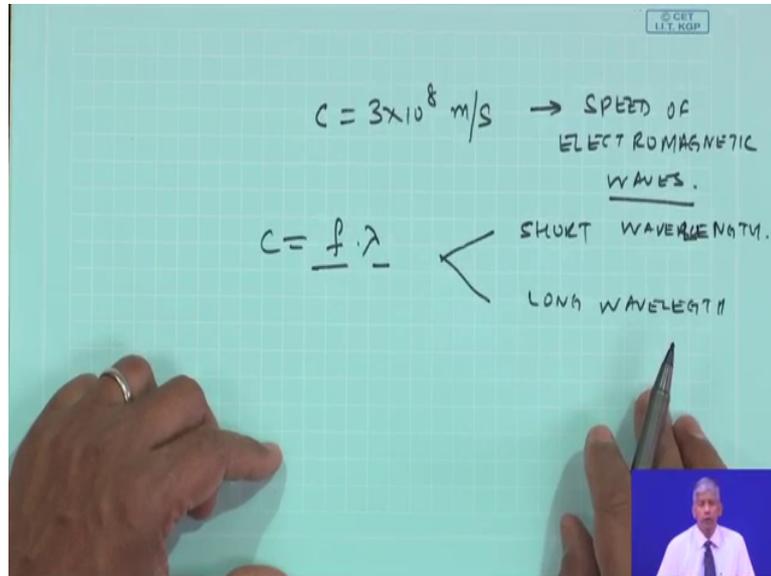

- Bodies give out Infrared radiations
- The infrared energy is dependent on the absolute surface temperature
- The infrared energy is dependent on the surface emissivity
- Semiconductors are used to measure the infrared energy

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, the principle of thermography is bodies actually give out infrared radiations, you know these are electromagnetic radiations like, we have the visible light anywhere from 4000 to 7000 angstroms is the wavelength and by the way this visible light or

electromagnetic waves travel at the speed of light 3×10^8 meters per second and later on we will see the entire spectrum.

(Refer Slide Time: 04:05)

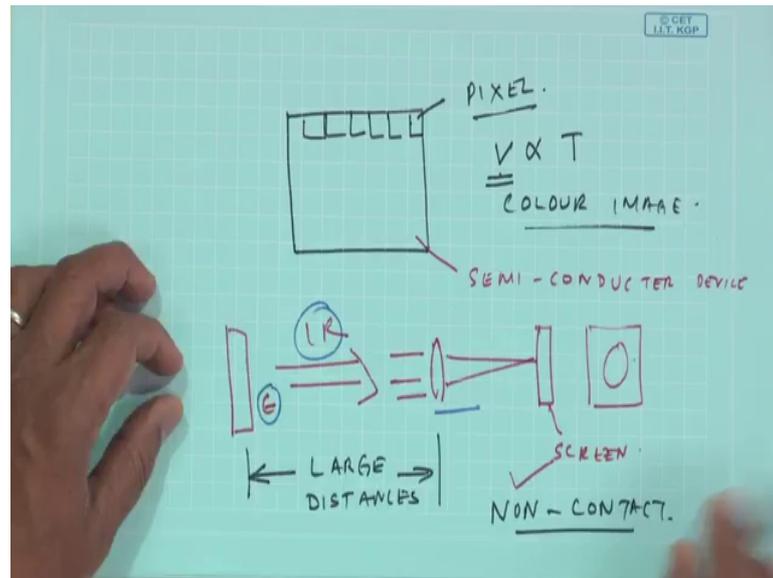

So, depending on the frequency, you know C is equal to depending on the frequency of the wavelength, we can classify a short wavelength long wavelength you know and so on. So, if wavelength is high the frequency is low and wavelength is short the frequency is high.

So, if we talk about you know TV signals, radio signals, gamma rays, X-rays you know ultraviolet rays, infrared bodies always give out infrared radiation and this infrared energy is dependent on the absolute surface temperature, you will recall there is a nice law in heat transfer the Stefan Boltzmann law, which we will discuss in a later on and of course, this infrared energy is dependent on the surface emissivity and there are certain special types of semiconductors on which if this infrared energy is incident they will develop a voltage ok.

So, that is essentially the principle beyond thermography.

(Refer Slide Time: 05:41)

So, if I have a screen, on to which infrared radiations are focused and they are pixel by pixel each pixel and they will generate a voltage proportional to the temperature of the body surface temperature. So, if the; you know body is hot you can have a different voltage and then you can you know colour image them. So, it is only because of these particular semiconductor devices.

So, basically I have a body which is giving out infrared radiations. So, this depends on the surface emissivity I have some optical systems which will focus all this into a screen which is made of a semiconductor device and this screen looks like this will give you a voltage which could be in and in through a software you can get an image which could be colour coded. So, the body's temperature you will get.

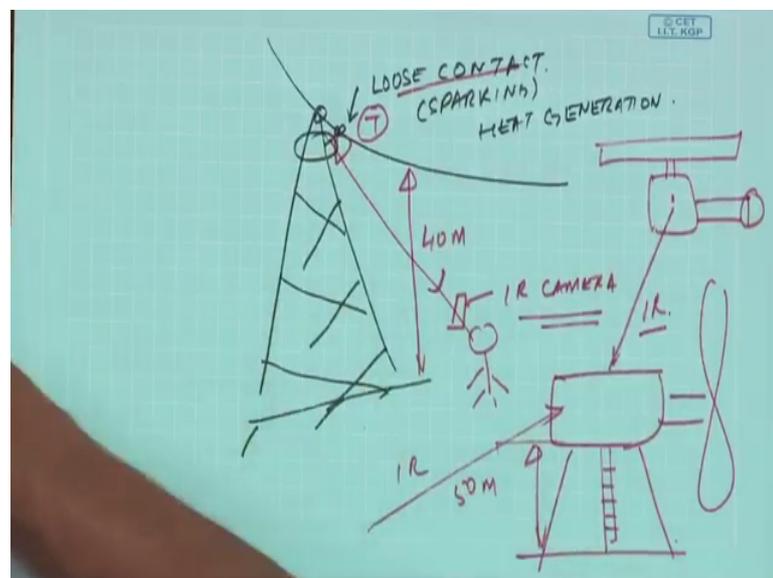

So, this is essentially how the principal I mean the thermography principal works and we will see what sort of a body conditions is important how do we estimate IR in a emissivity how do we calibrate this and what kind of camera system we require to get an image.

And the practical applications of thermography are tremendous because the ease at which you can measure because this can be at large distances and that is the essential advantage of thermography large distances and they are non contact imagine you have you know in the last class, I was just mentioning about condition mounting of switch gears imagine you have a large transmission power and it is carrying a conductor with a

switch gear and some sort of contact, it has to make because there are insulators are not going to talk about them suppose there is a loose contact. So, with loose contact there will be lot of sparking and there will be heat generation.

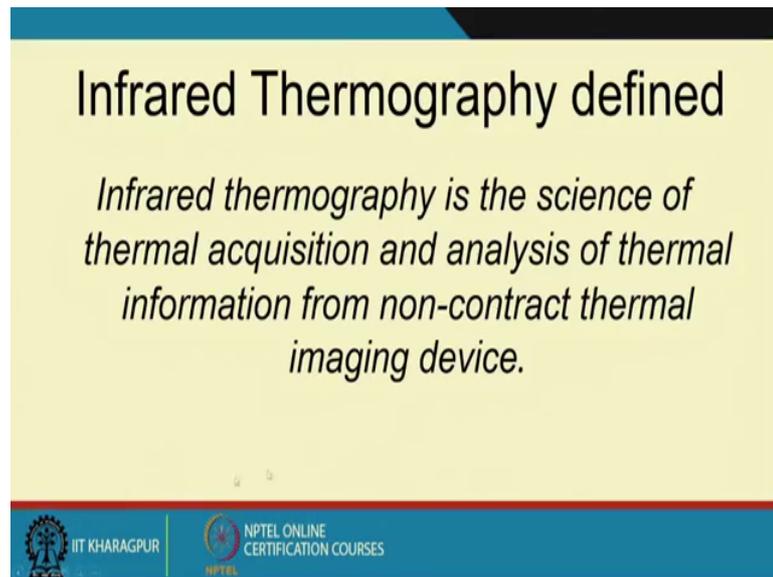

So, we can we can be standing here on the ground and this could be you know maybe forty meters from the ground. So, it could always shoot an IR beam and put a hold a camera IR camera and measure this temperature and if it is high than the other transmission towers or it is higher than the ambient you know a loose contact is occurred otherwise you imagine how do you detect such loose contacts you will see lot of voltage drops etcetera.

(Refer Slide Time: 09:20)

So, this is one typical advantage of IR cameras and same is true for windmills suppose we have a windmill wherein we have a gear box mounted very high again this is maybe fifty meters from the ground. So, you know if somebody was to make a contact type measurement one has to climb up the stairs to go up to the gear box, but rather you can shoot from an IR. In fact, there have been cases where people shoot IR cameras from helicopters to monitor the temperature of a machine.

(Refer Slide Time: 10:30)

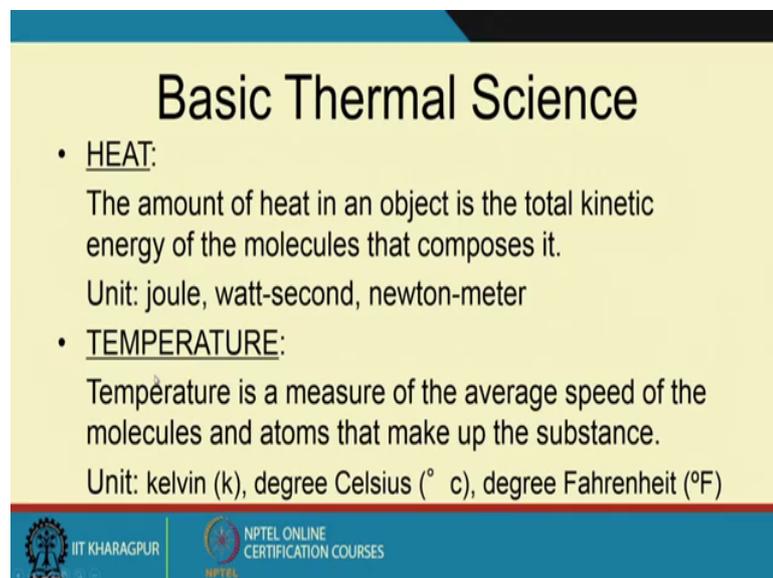

Infrared Thermography defined

Infrared thermography is the science of thermal acquisition and analysis of thermal information from non-contact thermal imaging device.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, infrared thermography is defined as the science of thermal acquisition and analysis of thermal information from non-contact thermal imaging device, it is non-contact.

(Refer Slide Time: 10:46)

Basic Thermal Science

- HEAT:
The amount of heat in an object is the total kinetic energy of the molecules that compose it.
Unit: joule, watt-second, newton-meter
- TEMPERATURE:
Temperature is a measure of the average speed of the molecules and atoms that make up the substance.
Unit: kelvin (k), degree Celsius ($^{\circ}$ c), degree Fahrenheit ($^{\circ}$ F)

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, you all know this is just a recap: the amount of heat in an object is the total kinetic energy of the molecules that compose it in joules, and temperature is a measure of the average speed of the molecules and atoms that make up this substance. Ok.

(Refer Slide Time: 11:03)

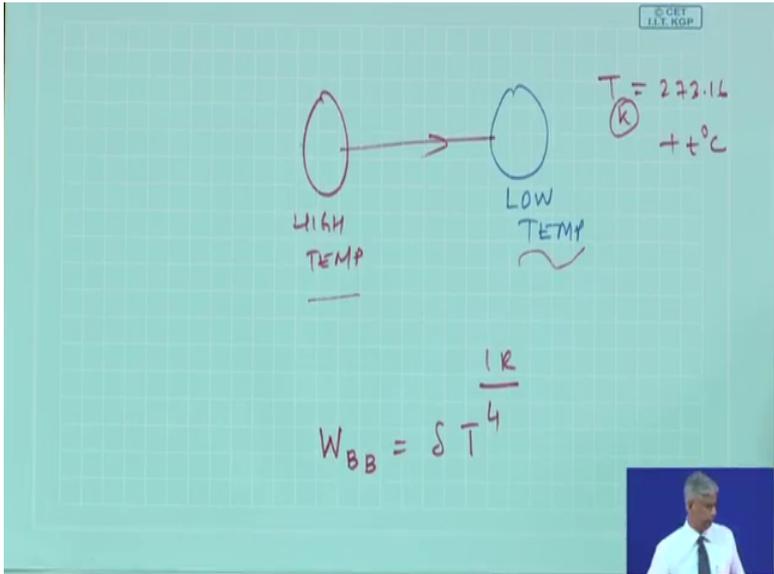

What is temperature?

- Temperature defines the state an object is in, relative to other objects.
- Temperature is not a form of energy
- Temperature will rise and fall as energy in an object increases and decreases. It is consequence of more or less energy.
- Temperature of the objects will tell us how easy it will give away heat to others.

 IIT KHARAGPUR |  NPTEL ONLINE CERTIFICATION COURSES

So, temperature defines the state an object is in relative to other objects. So, temperature is an indicator of energy though it is not a form of energy. So, temperature will rise and fall as energy in an object increases and decreases it is a consequence of more or less energy. So, temperature of the objects will tell us how easy it is give away heat to others somebody at a higher temperature will; obviously, energy heat energy will flow from a high temperature body to a low temperature body ok.

(Refer Slide Time: 11:35)

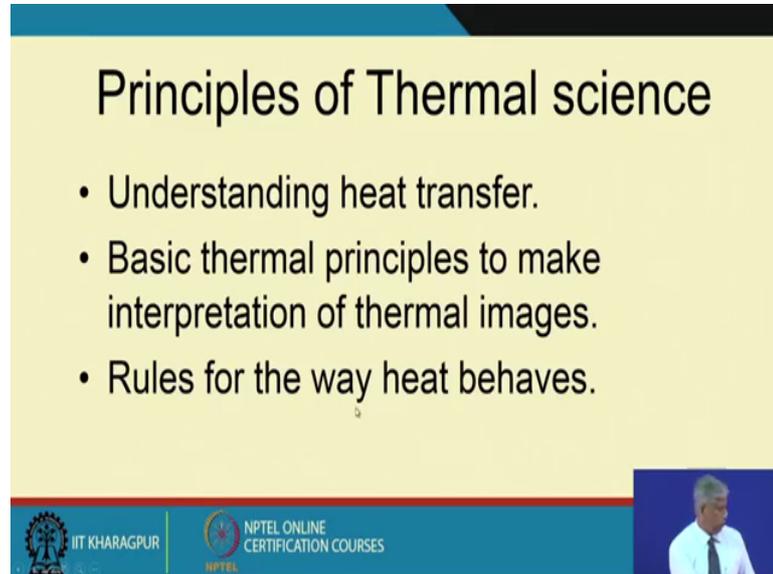

© IIT KGP

$T = 273.16 + t^{\circ}\text{C}$
K

$W_{BB} = \sigma T^4$
1 R

But if they are at equilibrium they all will be same. So, to see any momentary rise in temperatures or in rise in temperature above the normal, we can use IR thermography.

(Refer Slide Time: 12:05)

Principles of Thermal science

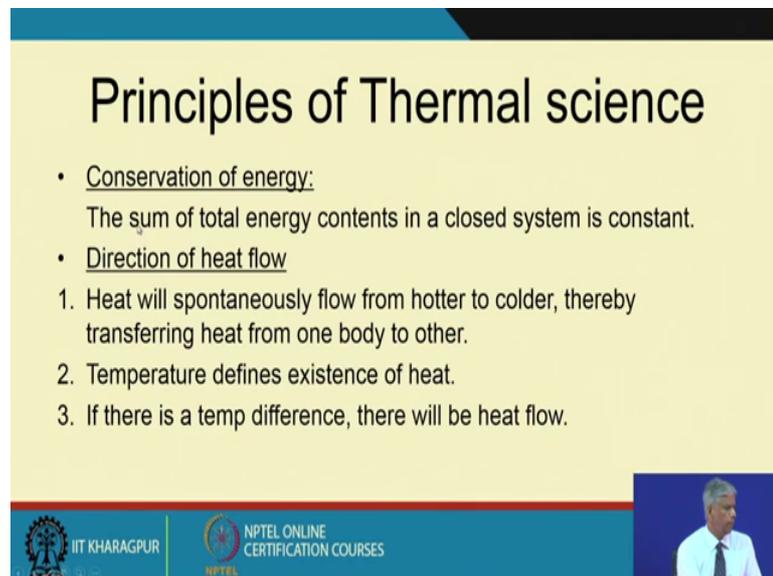

- Understanding heat transfer.
- Basic thermal principles to make interpretation of thermal images.
- Rules for the way heat behaves.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

NPTEL

NPTEL

(Refer Slide Time: 12:09)

Principles of Thermal science

- Conservation of energy:
The sum of total energy contents in a closed system is constant.
- Direction of heat flow
 1. Heat will spontaneously flow from hotter to colder, thereby transferring heat from one body to other.
 2. Temperature defines existence of heat.
 3. If there is a temp difference, there will be heat flow.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

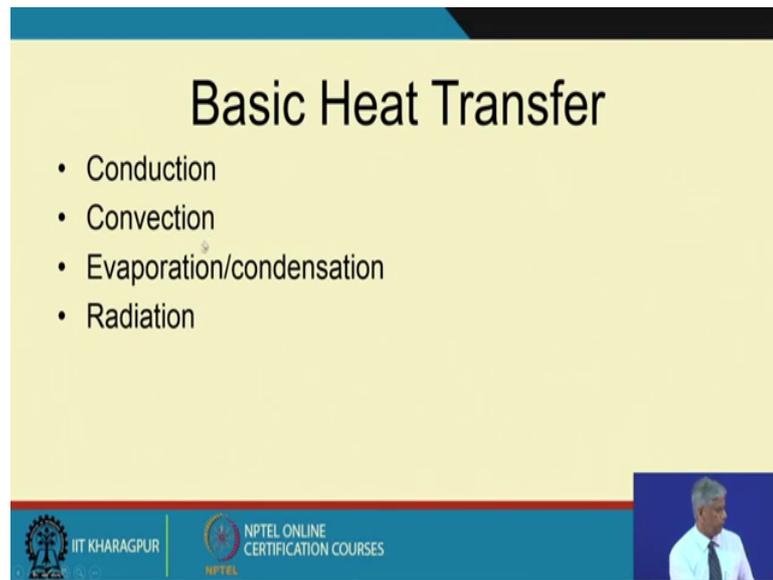

NPTEL

NPTEL

So, all the modes of heat transfer does work, the direction of heat flow heat flow heat will spontaneously flow from hotter to colder thereby transferring heat from one body to another.

So, temperature defines the existence of heat and if there is a temperature difference there will be a heat flow.

(Refer Slide Time: 12:29)

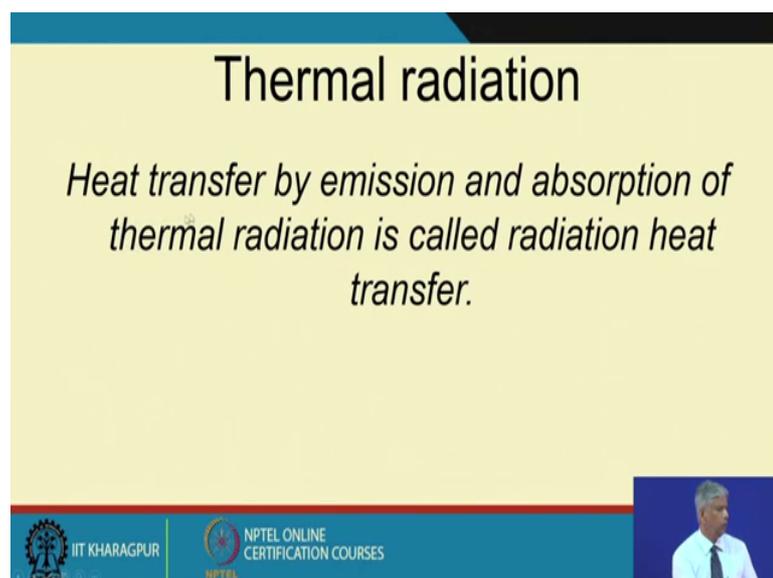

Basic Heat Transfer

- Conduction
- Convection
- Evaporation/condensation
- Radiation

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

The slide features a yellow background with a blue header and footer. The title 'Basic Heat Transfer' is centered at the top. Below it, a bulleted list contains four items: Conduction, Convection, Evaporation/condensation, and Radiation. The footer includes the IIT Khargapur logo and the NPTEL Online Certification Courses logo. A small inset video of a speaker is visible in the bottom right corner.

(Refer Slide Time: 12:32)

Thermal radiation

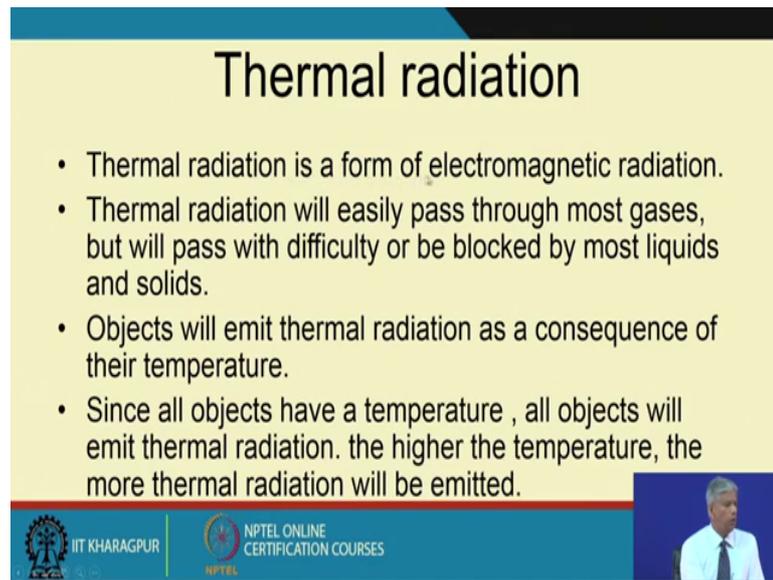

Heat transfer by emission and absorption of thermal radiation is called radiation heat transfer.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

The slide features a yellow background with a blue header and footer. The title 'Thermal radiation' is centered at the top. Below it, a paragraph in italics defines thermal radiation as heat transfer by emission and absorption. The footer includes the IIT Khargapur logo and the NPTEL Online Certification Courses logo. A small inset video of a speaker is visible in the bottom right corner.

So, basic mode of heat transfer are these three modes heat transfer by emission and absorption of thermal radiation is called radiative heat transfer and this is what we are going to focus on.

(Refer Slide Time: 12:44)

Thermal radiation

- Thermal radiation is a form of electromagnetic radiation.
- Thermal radiation will easily pass through most gases, but will pass with difficulty or be blocked by most liquids and solids.
- Objects will emit thermal radiation as a consequence of their temperature.
- Since all objects have a temperature, all objects will emit thermal radiation. the higher the temperature, the more thermal radiation will be emitted.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

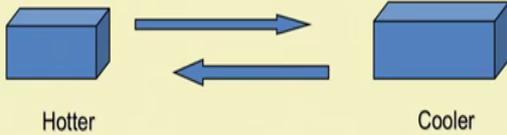

So, this thermal radiation is a form of electromagnetic radiation thermal radiation will easily pass through most gases, but will pass with difficulty or be blocked by most liquids and solids.

So, objects will emit thermal radiation as a consequence of the temperature. So, since all objects have a temperature all objects will emit thermal radiation the higher the temperature the more thermal emission thermal radiation will be emitted. So, our objective is to measure this infrared emitted radiative thermal energy by a system which is usually this thermal-imaging camera which essentially has a semiconductor device onto which this thermal energy is focused and this thermal semiconductor device on a pixel to pixel basis is going to give us a proportional voltage and through the appropriate software we could have a 2D image wherein we can have a colour image of the body whose temperature is being measured.

(Refer Slide Time: 13: 50).

Thermal radiation heat transfer

- Heat transfer by emission and absorption
- Both objects emit and absorb radiation
- Net heat transfer is the difference between the two.

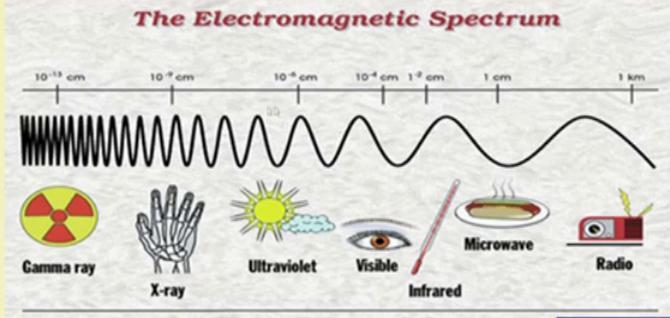

Hotter Cooler

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES

So, heat transfer is by emission and absorption both objects emit and absorb radiation. So, there is no heat transfer is the difference between the two; now I just mentioned about this infrared.

(Refer Slide Time: 14:00)

The Electromagnetic Spectrum

The Electromagnetic Spectrum

10⁻¹⁰ cm 10⁻⁹ cm 10⁻⁸ cm 10⁻⁷ cm 1⁻⁶ cm 1 cm 1 km

Gamma ray X-ray Ultraviolet Visible Infrared Microwave Radio

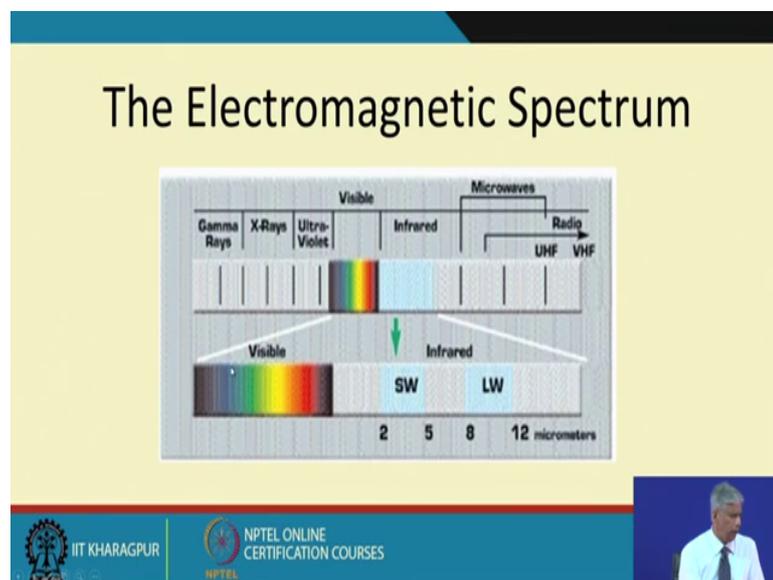

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES

So, the electromagnetic spectrum, if you see at the high frequencies know, we have very low wavelengths and then we have relatively high wavelengths and the frequencies are lower relatively.

So, beyond just after the visible range we have what is known as the narrow infrared region where is very easily this infrared energy can influence a semiconductor some of this energies you know and these waves have very very high power and they are used for penetrating metals x-rays or penetrating solid devices where this cannot ok.

So, depending on the frequency, the intensity of this energy is can be calculated and infrareds are that way not harmful and they can be used to measure the temperature of a body, we will see how.

(Refer Slide Time: 15:11)

So, infrared, if this is the typical reason wherein infrared in terms of the micrometers you can say from 2 to about 12 micrometers is the wavelength of infrared waves.

(Refer Slide Time: 15:30)

Thermal Radiation

- *Thermal radiation occurs in part of the electromagnetic spectrum that begin somewhere within UV band and continues through out all of the visible and infrared wavebands.*
- Visible – 0.4-0.7 μm
- Near IR ~ 1 μm
- Short wave IR – 2- 5 μm
- Long wave – 8-14 μm

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

NPTEL

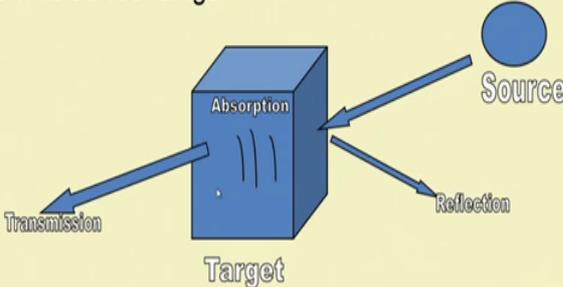

So, thermal radiation occurs in part of the electromagnetic radiation that begins somewhere within the UV band and continues throughout all of the visible infrared wavelengths wavebands. So, visible is you know about 4000 to 7000 angstrom near infrared about 10,000 angstrom and then short wavelength long wavelength and so on.

(Refer Slide Time: 16:00)

Incident radiation

- Incident radiation is all the radiation that strikes an object from its surroundings

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

NPTEL

So, when an incident energy is striking a body, from it will absorb something, it will reflect and it will transmit.

(Refer Slide Time: 16:23).

Exitant radiation

- *Exitant radiation is all the radiations that leave the surface, regardless its source*

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, this emission is this radiation that leads the surface regardless of its source. So, we are trying to measure this emission.

(Refer Slide Time: 16:40)

Exitant radiation

- Of the total exitant radiation from a target a certain proportion will be
 1. Emitted, from the object itself
 2. Reflected, from a source in front of the object
 3. Transmitted, from a source behind the object

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, Exitant radiation is the total radiation from a target a certain proportion will be emitted from the object itself reflected from the source in front of the object transmitted source from behind the object.

(Refer Slide Time: 16:54)

Exitant radiation

- Total radiation energy is a combination of
- Emitted
- Reflected
- Transmitted
- $\epsilon + \rho + \tau = 1$

So, total energy is nothing, but a combination of emitted reflected and transmitted.

(Refer Slide Time: 17:00)

Radiated energy and temperature

- Something we must remember...
- ...that camera detects electromagnetic radiation in a certain wavelength.

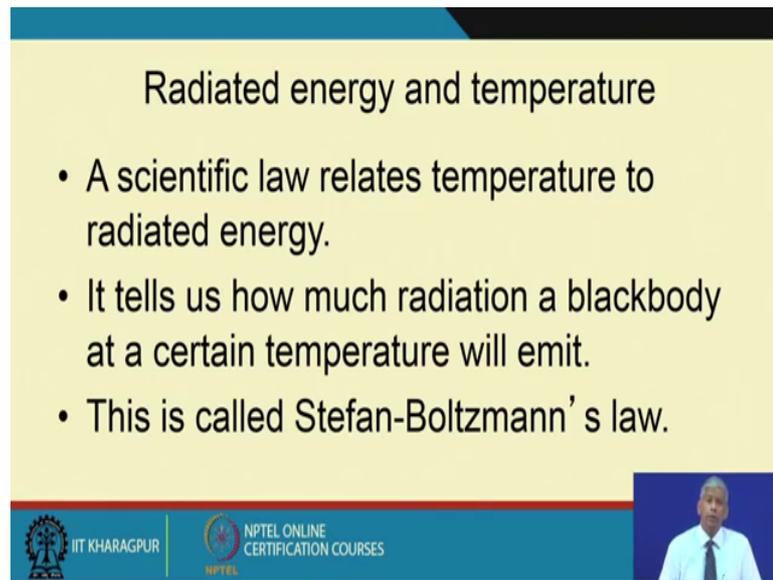

- ...and we want to measure something different i.e. Temperature

So, this camera; this is typically a hand infrared camera which is being held ok. So, an object is emitting infrared radiations and we can measure it.

(Refer Slide Time: 17:16)

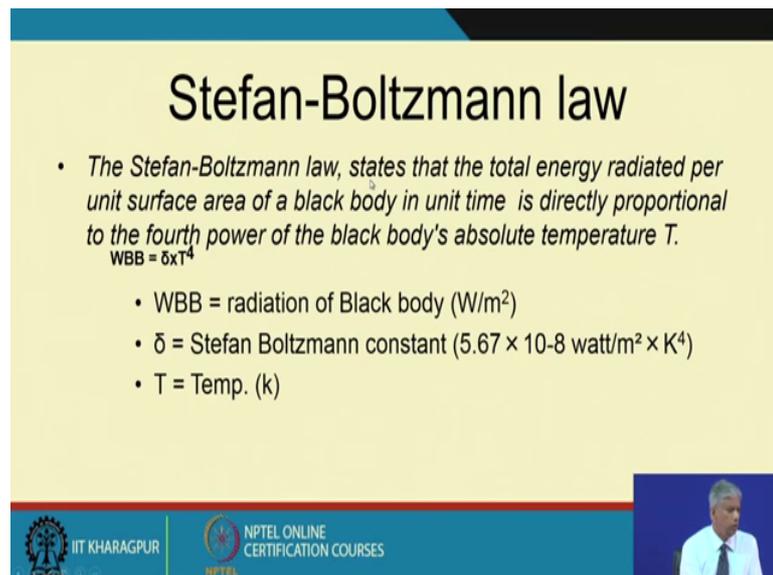

Radiated energy and temperature

- A scientific law relates temperature to radiated energy.
- It tells us how much radiation a blackbody at a certain temperature will emit.
- This is called Stefan-Boltzmann's law.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, this scientific law which I just mentioned before relates temperature to the radiative energy and it tells us how much radiation a blackbody at a certain temperature will emit and all of you perhaps will recall from your high school physics that this is called the Stefan-Boltzmann law and the Stefan-Boltzmann law states that the total energy radiated per unit surface area of a black body in unit time is directly proportional to the fourth power of the black body's absolute temperature capital T.

(Refer Slide Time: 17:38)

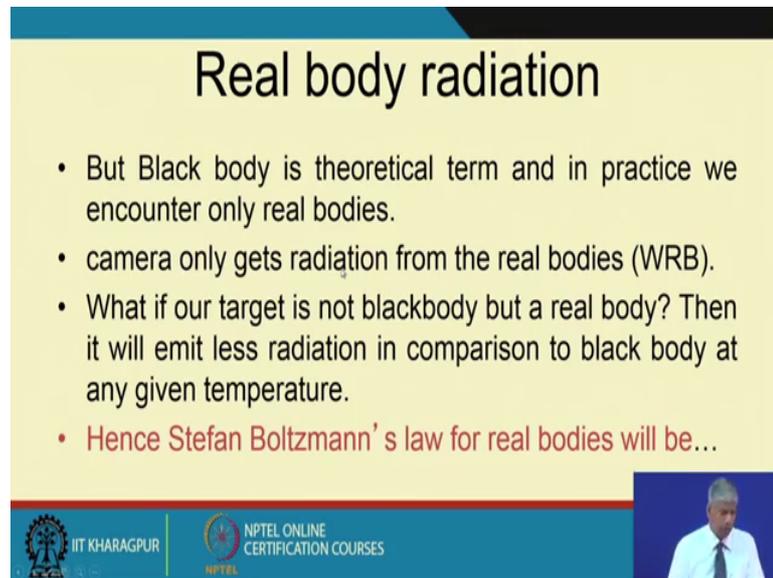

Stefan-Boltzmann law

- *The Stefan-Boltzmann law, states that the total energy radiated per unit surface area of a black body in unit time is directly proportional to the fourth power of the black body's absolute temperature T.*
$$W_{BB} = \delta \times T^4$$
- WBB = radiation of Black body (W/m^2)
- δ = Stefan Boltzmann constant ($5.67 \times 10^{-8} \text{ watt/m}^2 \times K^4$)
- T = Temp. (k)

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, this energy w blackbody is nothing, but where T is 273.16 plus T in degree Celsius whole thing in T is in Kelvin and this is an universal constant the Stefan Boltzmann constant.

(Refer Slide Time: 18:24)

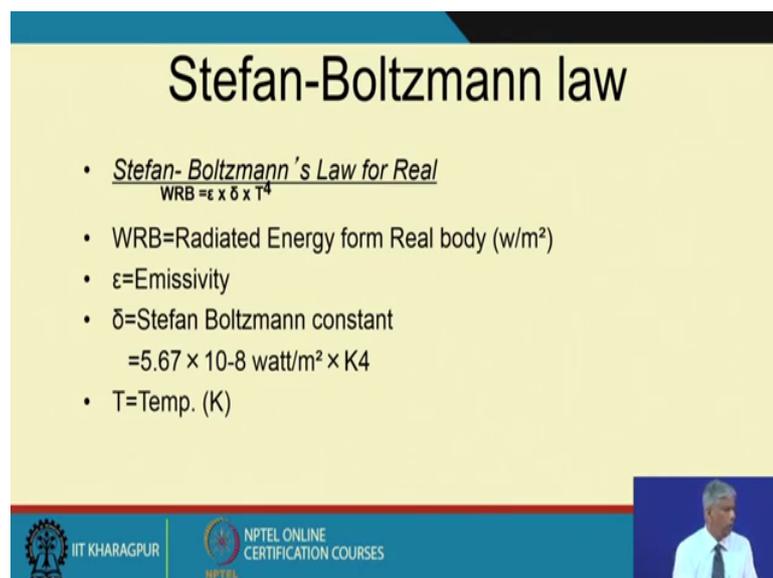

Real body radiation

- But Black body is theoretical term and in practice we encounter only real bodies.
- camera only gets radiation from the real bodies (WRB).
- What if our target is not blackbody but a real body? Then it will emit less radiation in comparison to black body at any given temperature.
- Hence Stefan Boltzmann's law for real bodies will be...

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, but you know this blackbody is something very theoretical, but we have a real body where the emissivity is not equal to 1. So, then it will give less emission or radiation in comparison to blackbody and Stefan-Boltzmann for real bodies will be this, ok.

(Refer Slide Time: 18:47)

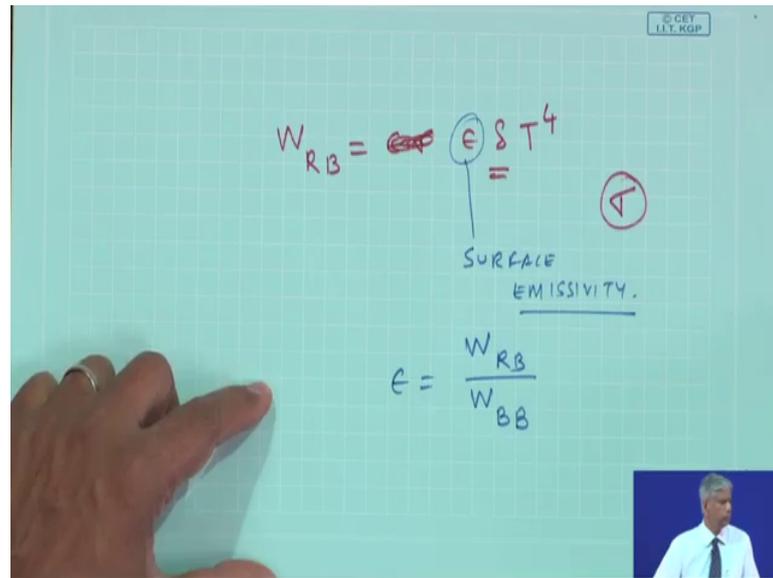

Stefan-Boltzmann law

- Stefan-Boltzmann's Law for Real
 $WRB = \epsilon \times \delta \times T^4$
- WRB=Radiated Energy form Real body (w/m²)
- ϵ =Emissivity
- δ =Stefan Boltzmann constant
 $= 5.67 \times 10^{-8} \text{ watt/m}^2 \times \text{K}^4$
- T=Temp. (K)

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

(Refer Slide Time: 19:06)

So, we see this for the real body w real body is nothing, but surface emissivity times, sorry, Boltzmann constant, I have denoted this and some book you will see the symbol this ok.

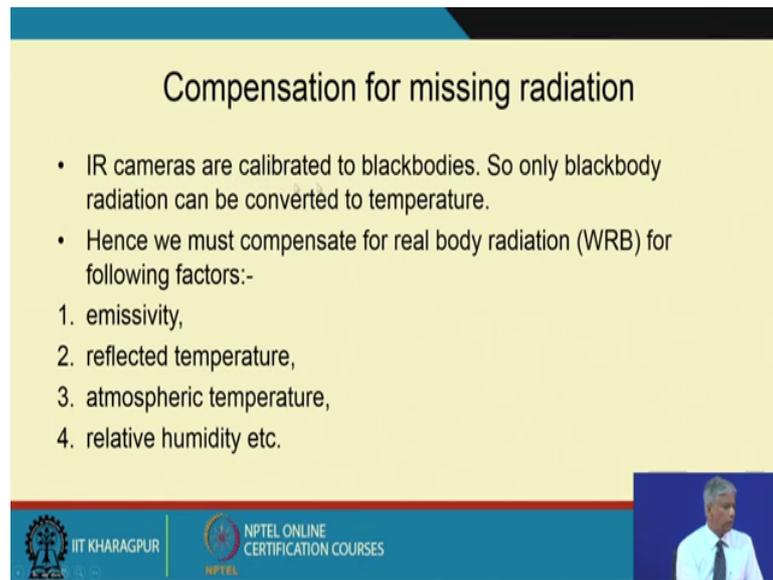

So, the idea is; how do I find out the emissivity of a real body. So, one which we will talk about emissivity; so, emissivity; obviously, will be nothing, but.

(Refer Slide Time: 19:57)

The slide is titled "Emissivity defined". It contains a bullet point defining emissivity as the ratio of radiation emitted by a real body compared to a blackbody at the same temperature and wavelength. Below the definition is the formula $\epsilon = W_{RB} / W_{BB}$. The slide footer includes the IIT Kharagpur logo and the NPTEL Online Certification Courses logo.

So, it is the ratio of radiated emitted radiation emitted by a real body compared to the radiation emitted by a blackbody at the same temperature and same wavelength.

(Refer Slide Time: 20:08)

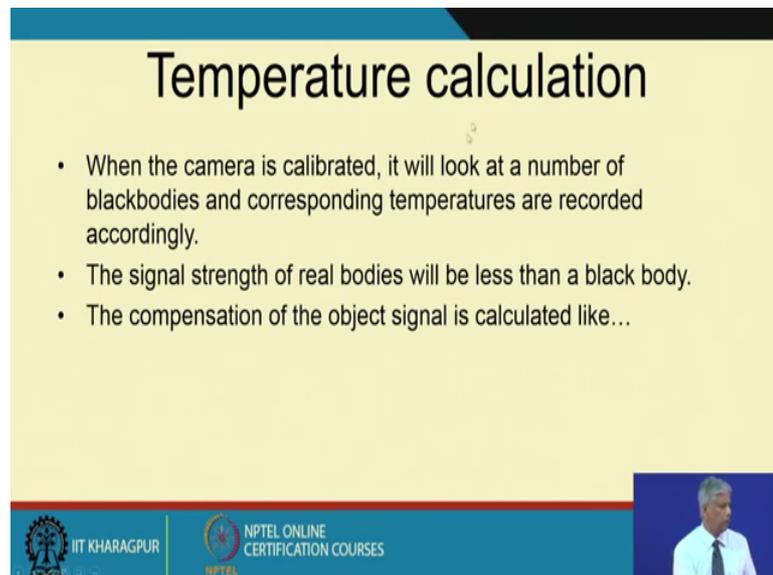

Compensation for missing radiation

- IR cameras are calibrated to blackbodies. So only blackbody radiation can be converted to temperature.
- Hence we must compensate for real body radiation (WRB) for following factors:-
 1. emissivity,
 2. reflected temperature,
 3. atmospheric temperature,
 4. relative humidity etc.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, IR cameras are calibrated to blackbody. So, only blackbody radiation can be converted to temperature. So, hence we must compensate for real body by the following factors emissivity temperature reflected temperature sorry, emissivity reflected temperature, atmospheric temperature, humidity so on.

(Refer Slide Time: 20:35)

Temperature calculation

- When the camera is calibrated, it will look at a number of blackbodies and corresponding temperatures are recorded accordingly.
- The signal strength of real bodies will be less than a black body.
- The compensation of the object signal is calculated like...

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

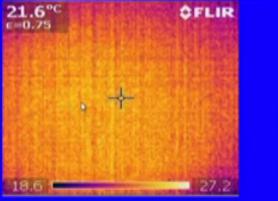

So, we have to calculate and compensate for the real body, ok.

(Refer Slide Time: 20:39)

What is thermography?

Heat is the energy exchanged between systems having different temperatures.

So, when there is no temperature difference, the infrared image does not show any contrast and there is no possible analysis!

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, we will see how it is done. So, if the bodies are in the same temperature, there will be no colour contrast because there is no temperature difference.

(Refer Slide Time: 20:51)

Emissivity

Thermal and electrical insulators are excellent emitters.
Measurement is not a problem.

Metals are poor emitters.
Unless heavily oxidised, emissivity is rarely superior to 0.25.
Measurement is delicate.

Woods	Rubber
Plastic	PVC
Soil	Porcelain
Paper	Concrete
Painted surfaces	
Building materials	

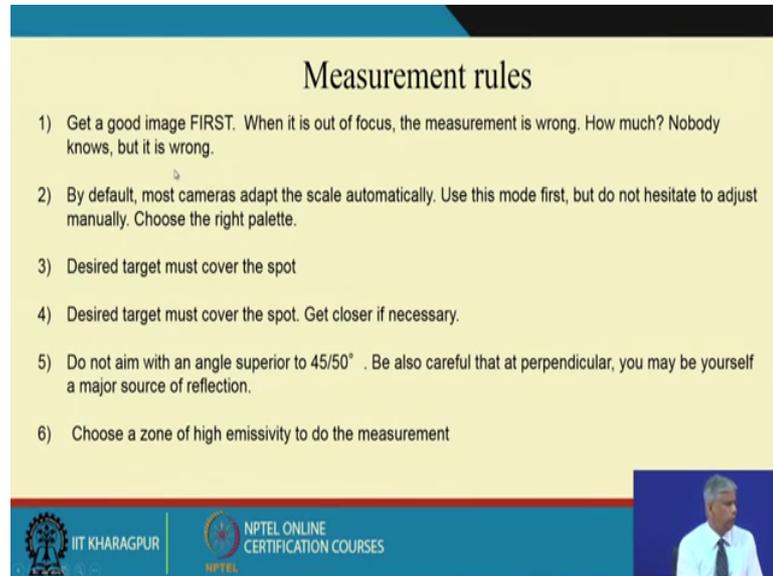

Copper	Steel
Iron	Brass
Soil	Nickel
Zinc	Lead
Aluminium	
Chromium	

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, coming back to the emissivity sorry thermal and electrical insulators are excellent emitters. So, measurement is not a problem woods rubber plastic PVC soil paper painted surface building material porcelain concrete they are all having an high emissivity and then we can use this to measure the surface temperature by IR.

But metals are poor emitters unless heavily oxidized. So, emissivity is rarely superior to greater than 0.25 like all these metals or any shiny surfaces. So, that is what we have to careful about in one of the examples, I will show you how this is taken care off.

(Refer Slide Time: 21:37)

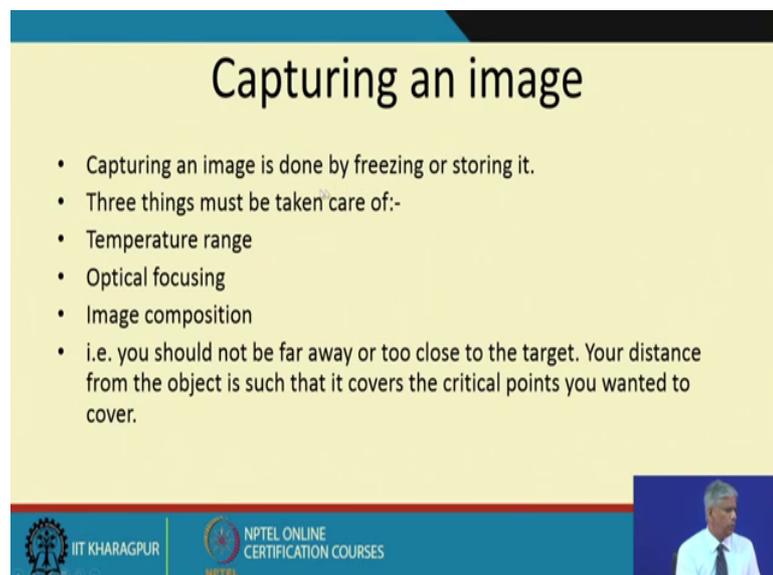

Measurement rules

- 1) Get a good image FIRST. When it is out of focus, the measurement is wrong. How much? Nobody knows, but it is wrong.
- 2) By default, most cameras adapt the scale automatically. Use this mode first, but do not hesitate to adjust manually. Choose the right palette.
- 3) Desired target must cover the spot
- 4) Desired target must cover the spot. Get closer if necessary.
- 5) Do not aim with an angle superior to $45/50^\circ$. Be also careful that at perpendicular, you may be yourself a major source of reflection.
- 6) Choose a zone of high emissivity to do the measurement

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, some of the measurement rule is get a good image first by this focusing system and then target must cover this part do not aim beyond this. So, that and try to measure in high-end emissivity and see make sure that your body reflection does not come on to you.

(Refer Slide Time: 22:00)

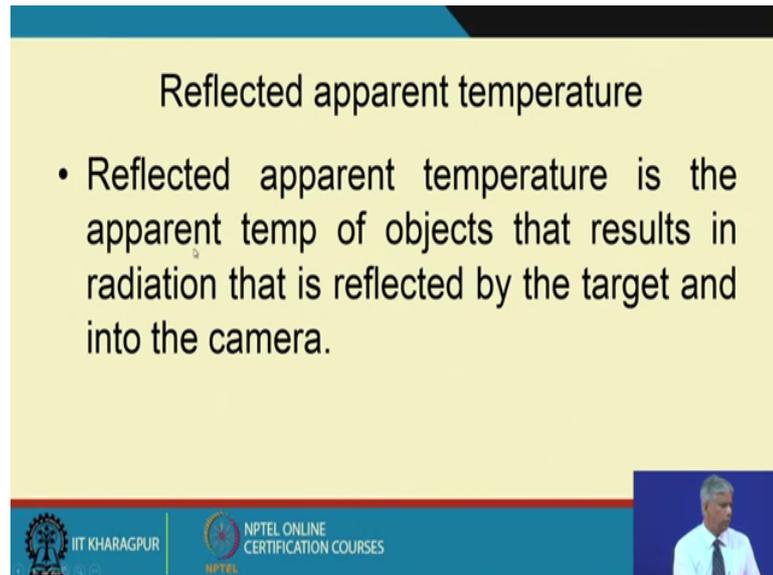

Capturing an image

- Capturing an image is done by freezing or storing it.
- Three things must be taken care of:-
- Temperature range
- Optical focusing
- Image composition
- i.e. you should not be far away or too close to the target. Your distance from the object is such that it covers the critical points you wanted to cover.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, capturing and images, freeze it you have to know about the temperature range the focusing and image composition, you should not be far away or too close to the target your distance from the object is such that it covers the critical points, you want to cover reflected apparent temperature the apparent temperature of bodies that result in radiation that is reflected by the target and into the camera. So, we have to careful about this.

(Refer Slide Time: 22:22)

Reflected apparent temperature

- Reflected apparent temperature is the apparent temp of objects that results in radiation that is reflected by the target and into the camera.

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES

So, measuring reflected temperature make sure that there is a reflecting what is reflecting in your target set the emissivity one and distance to 0, put a box with average temperature measurement note the temperature this is your T reference and measuring emissivity.

(Refer Slide Time: 22:49)

Measuring Emissivity

- Select a sample
- Put a piece of electrical tape with known emissivity.
- Heat the sample
- Focus & note the temp. at tape.
- Move your measurement function to the sample surface.
- Change the emissivity setting until your previously measured temp.
- Note the emissivity.

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

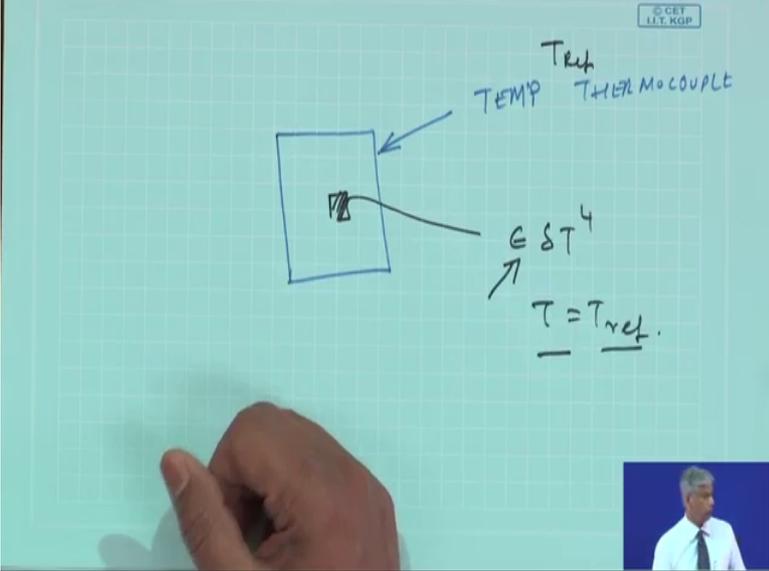

NPTEL

Select a sample, put a piece of electrical tape with known emissivity and heat the sample focus and note the temperature at tape and move your measurement function to a sample surface change the emissivity until and note the emissivity, this is a very simple way to do it, I will explain you how.

(Refer Slide Time: 23:12)

TEMP T_{ref} THERMOCOUPLE

$E \epsilon T^4$

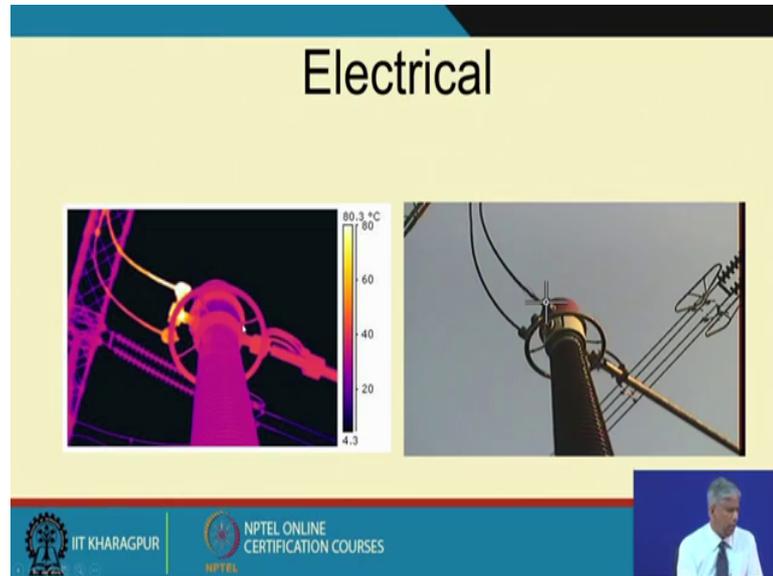

$T = T_{ref.}$

I will have a surface whose temperature is known to me, maybe by a thermocouple. So, I will put some sort of a patch and focus there and measure through I do not know the emissivity, I will measure through this and get a temperature ok. So, I will vary this

emissivity till I get this T equal to the T reference ok. So, this is all very easily you can know the emissivity of an unknown surface or many times, you can go to the handbooks and see the emissivity of different surfaces ok.

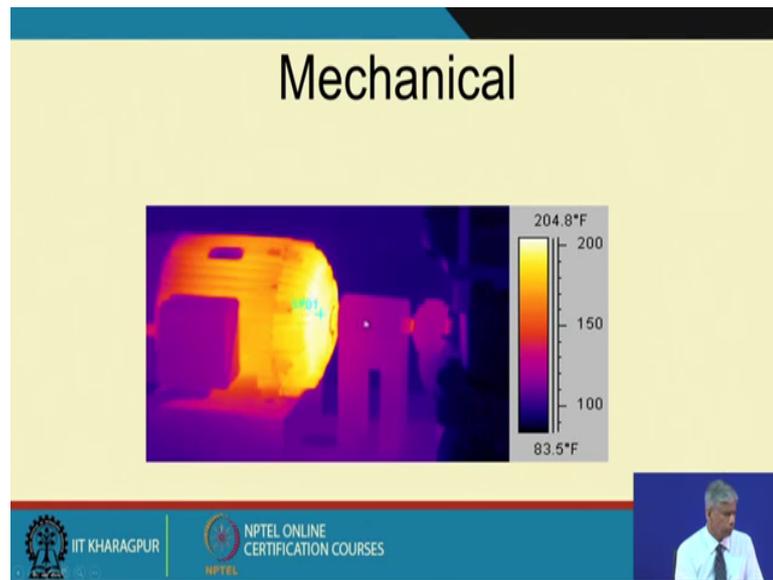

(Refer Slide Time: 24:07)

Now, I will show you some typical examples wherein in a colour code you can see typical measurements of these infrared thermal imaging cameras. So, this is an electrical switch gear wherein some loose contact is there and there is high up from the ground. So, we can have a thermal imaging camera and you can see the hot spots being measured by such thermal imaging camera while in operation.

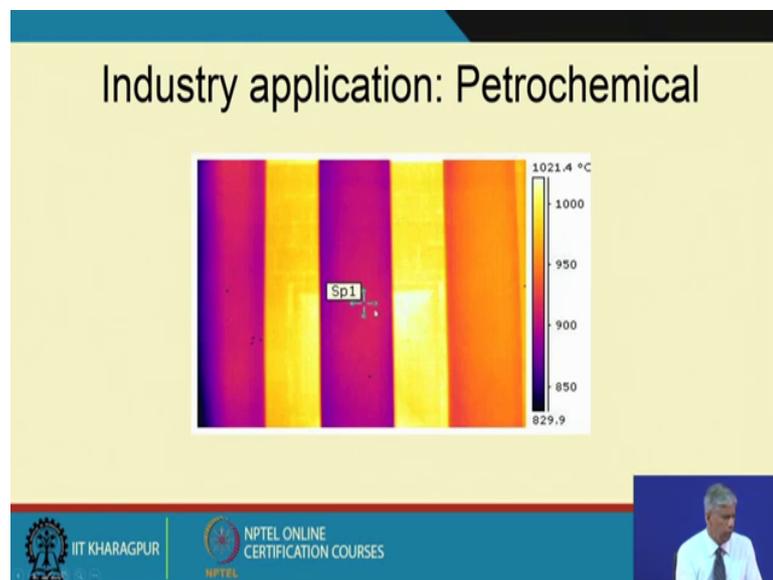

So, you know there is something happening here this temperature is very high ok, then later on you can go ahead and make some diagnostic measures as to how to reduce that a motor electrical motor drive in some unit.

(Refer Slide Time: 24: 50)

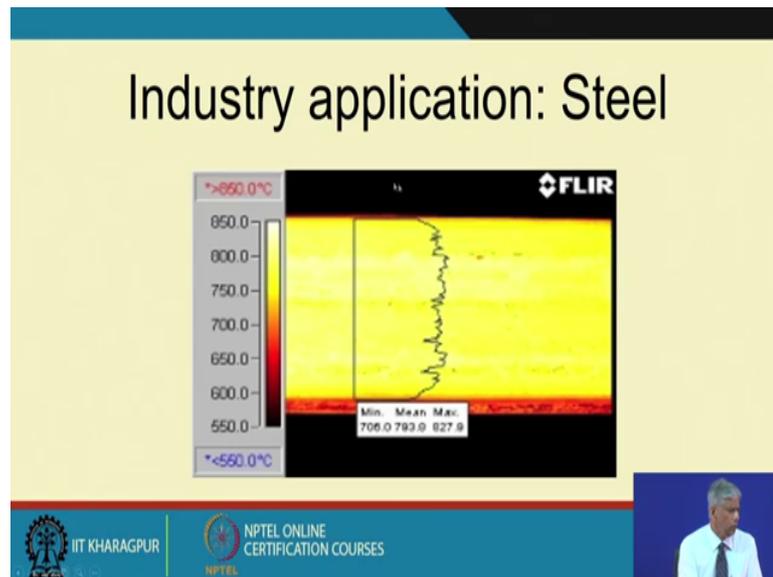

There is the high temperature here close to 200 degree Celsius, very easily we can measure from a distance that something is wrong at this end of the electrical motor ok.

(Refer Slide Time: 25:11)

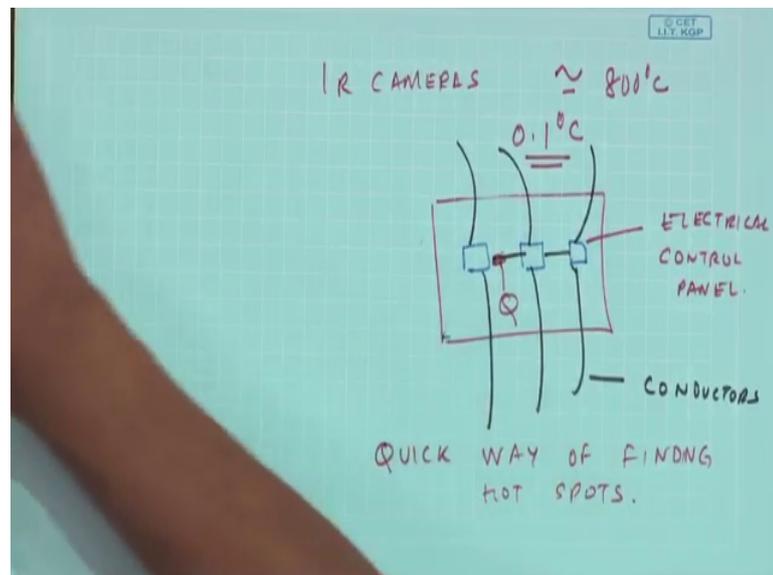

(Refer Slide Time: 25:22)

In petrochemical, if there is a variation in the temperature, you can see in any applications, what the temperature is application in steel mills rolling mills; we can measure through infrared temperatures with some of these IR cameras available in the market.

(Refer Slide Time: 25:34)

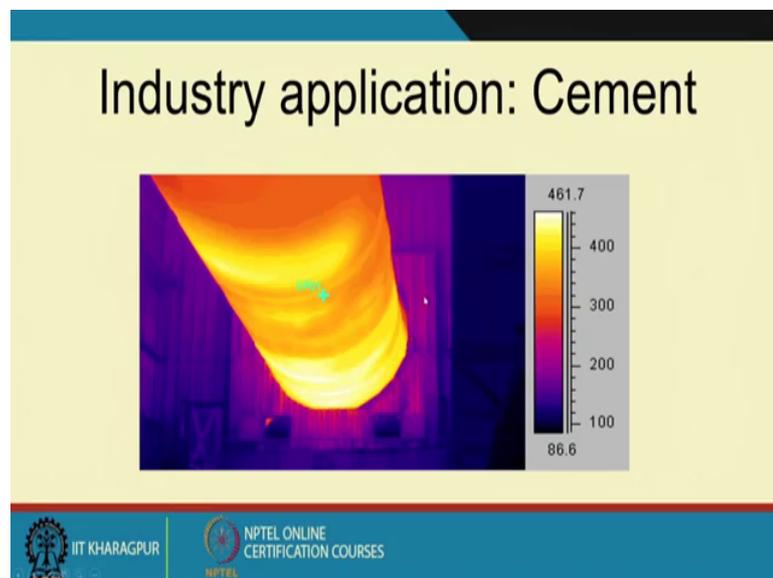

We can measure around 800 degrees Celsius with an accuracy of 0.1 degree Celsius imagine you know this is very powerful in the sense any place you want to measure you can very easily do it.

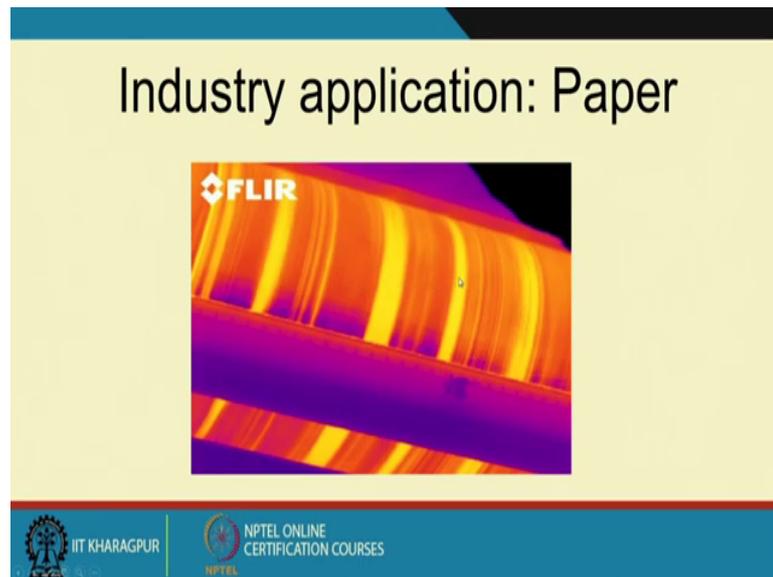

I will give you another example wherein electrical control panel very quickly you would like to know because you know you just have some few switches. So, and there are lot of conductors you know and the maze of conductors and this black conductors are not visible to you because they are behind this panel ok.

So, what can happen is you can always take a thermal image and suppose there is some short circuit or some loose connections. So, a lot of heat generation is there. So, by doing a quick thermal imaging scanning on the surface you can find out what the temperature of this area is and where the short circuit is, then later on you can do a diagnostic to find out why that short circuit happen.

(Refer Slide Time: 27:30)

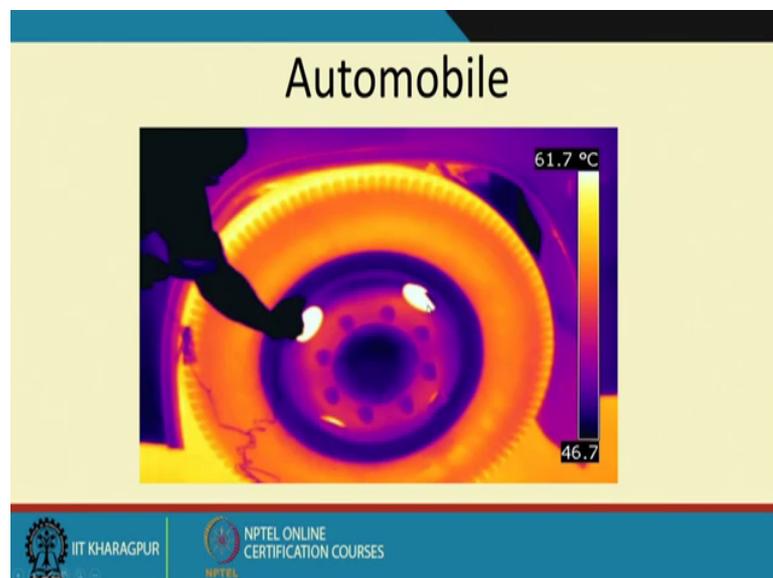

(Refer Slide Time: 27:35)

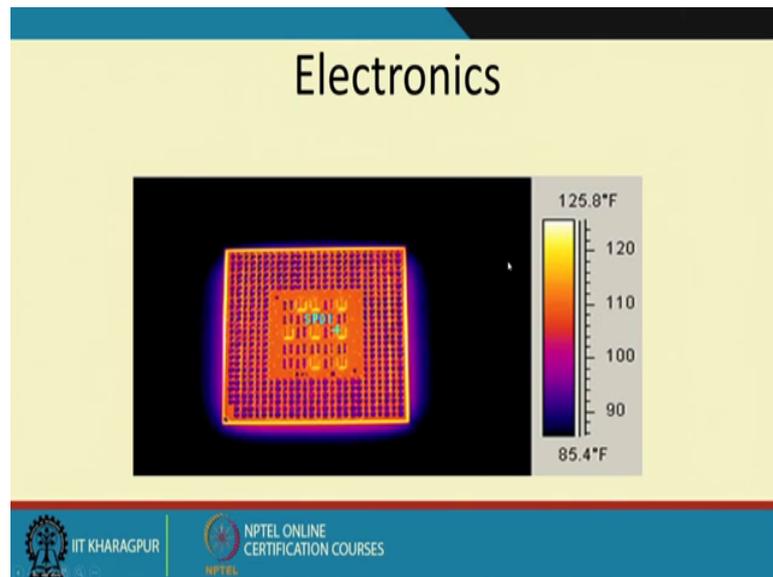

So, thermography is a very quick way of finding hot spots particularly in the cement plant in paper mills, you can say lot of hot areas are there.

(Refer Slide Time: 27:40)

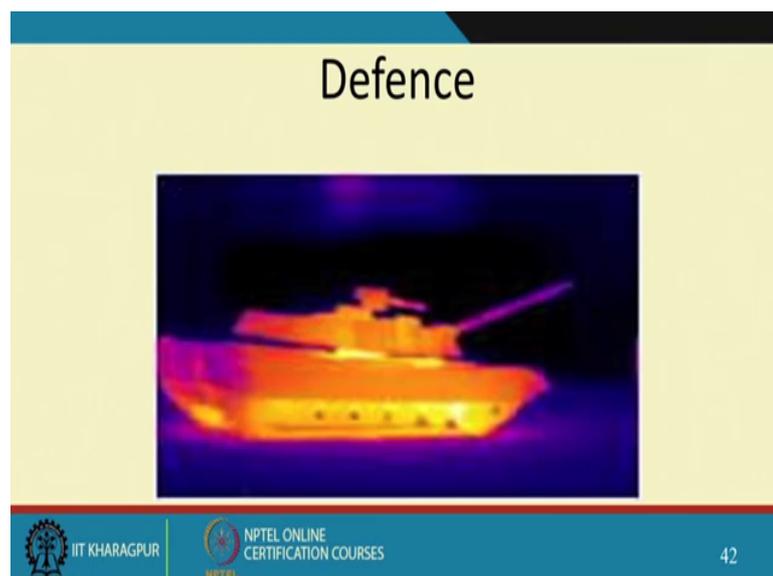

Neros automobile, you know for example, this brake drum or the rotor has heated, you can see very easily such things particularly in electronic circuits if some particular component is not getting power supply, it would not heat.

(Refer Slide Time: 27: 50)

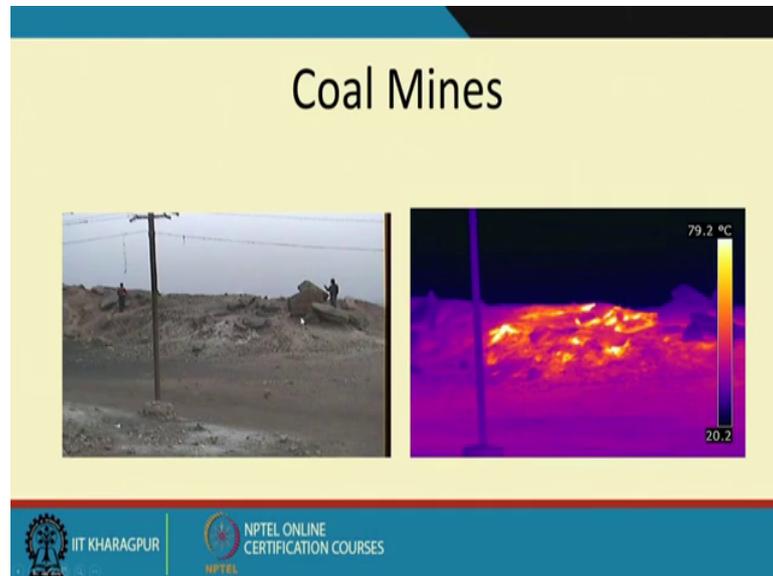

So, you can see some cold spots and then you can say, perhaps, this device semiconductor device or whatever this IC chip is dead because you know you know anywhere in a circuit, I will have this energy depending on the square of the current and that will be the heat generation. So, this I can very easily through a thermal imaging in a TV circuit, you can find out whether a semiconductor is not powder different surveillance, you know lot of IR cameras are used for surveillance, ok.

(Refer Slide Time: 28:29)

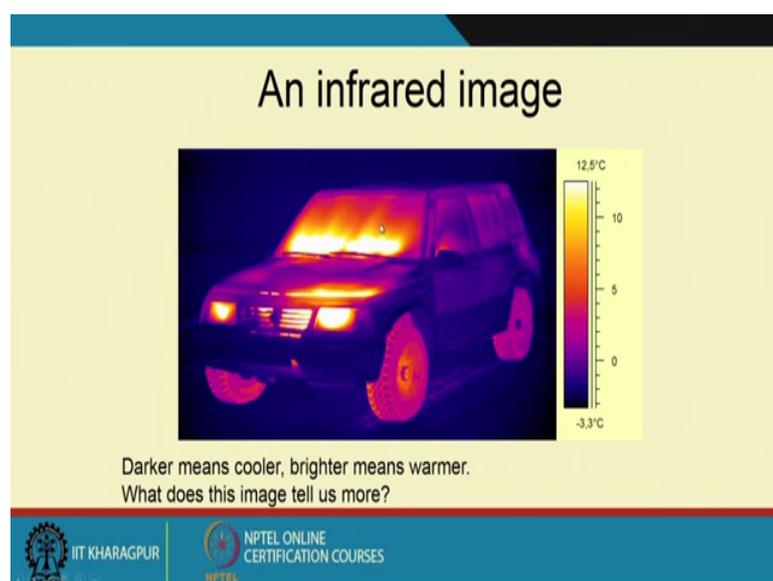

Finding out hot surfaces, you know, the cops running after robber, you know if somebody is running, you can find out the body temperatures rise.

(Refer Slide Time: 28:42)

For example, look at how elude in this temperatures could be you know in a coal mine vary of dumb, ok, there are a lot of hot spots ok, they all you can see slag has been deposited and then you can see underneath this you have very high temperature infrared image.

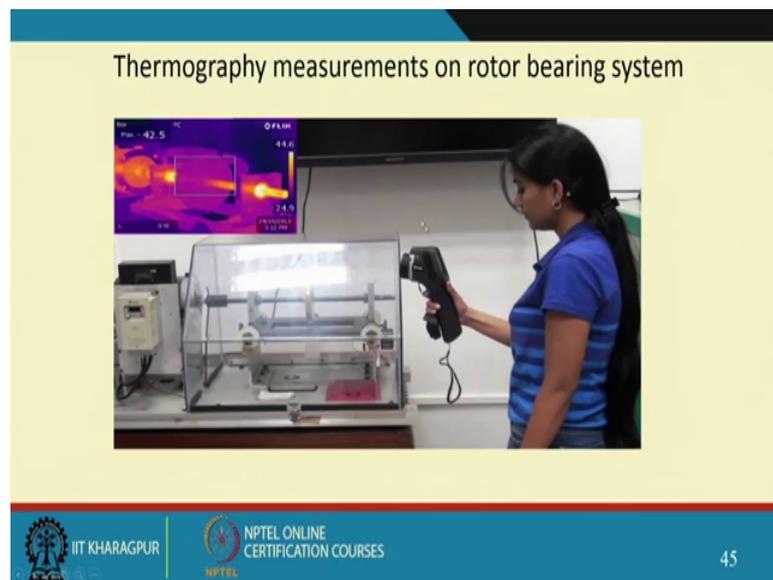

(Refer Slide Time: 29:04)

You can find out where there is a cold air conditioning this is a hot air coming out darker means cooler. So, this image says you know is the headlights engine is radiating heat the heater in the vehicle is running so that you can see lot of hot areas.

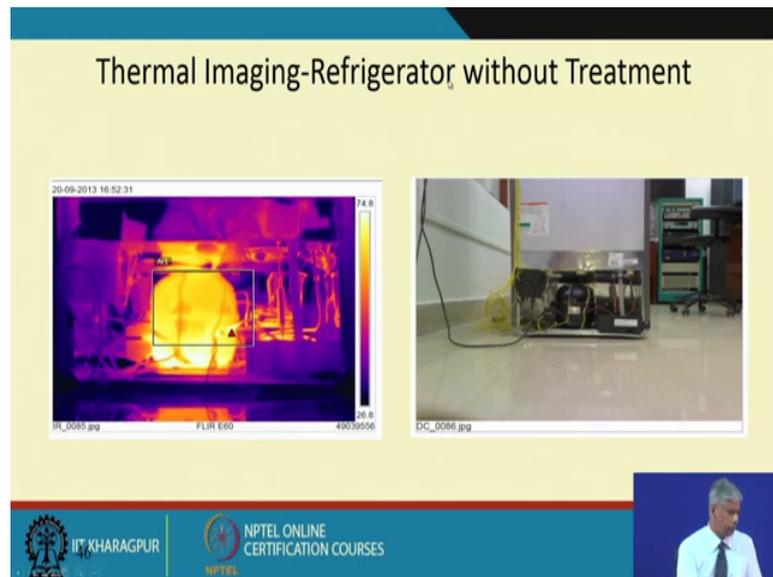

So, these are all very easy areas to find out maybe there is not enough heater coming out here you can find out where the flow is cold and flow is hot. So, maybe this passage is choke.

(Refer Slide Time: 29:43)

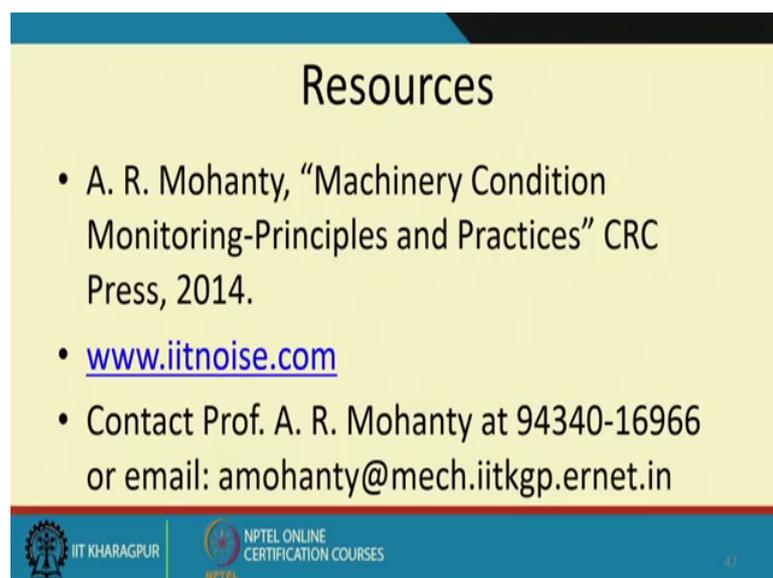

So, very quickly you can find out through thermal imaging, here in the laboratory, we are doing a thermal imaging to find out the bearings temperature rising because of a misalignment in the shaft and this is again in the laboratory wherein the backside of a refrigerator see this backside.

(Refer Slide Time: 29:53)

It is a metal, it is a very bad emitter, but this compressor is black and dull on the outside. So, it is a good emitter. So, you can very easily measure the temperature of the compressor and all the conductors by using a thermal imaging. So, these are some of the applications of thermography for finding out quick ways to find out faults and more of this, you will find in my book.

(Refer Slide Time: 30:27)

Thank you.
