Lecture - 24
Wave Mechanics of the Simple Harmonic Oscillator

(Refer Slide Time: 00:07)

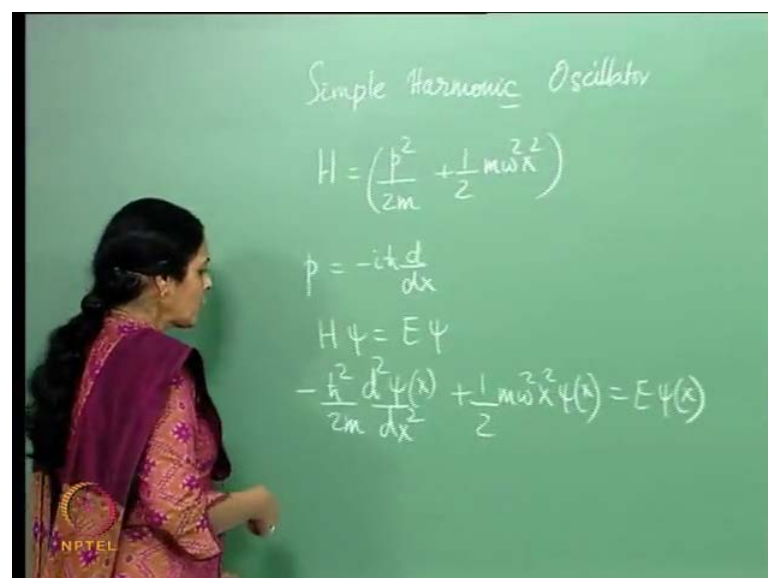

Keywords

- The eigenvalue equation
- Gaussian ground state
- Energy eigenvalues and eigenfunctions
- Hermite polynomials
- Parity

Now, in the last lecture we were looking at the simple harmonic oscillator and this was in the position representation.

(Refer Slide Time: 00:21)

Simple Harmonic Oscillator

$$H = \left(\frac{p^2}{2m} + \frac{1}{2} m \omega^2 x^2 \right)$$
$$p = -i\hbar \frac{d}{dx}$$
$$H\psi = E\psi$$
$$-\frac{\hbar^2}{2m} \frac{d^2\psi(x)}{dx^2} + \frac{1}{2} m \omega^2 x^2 \psi(x) = E\psi(x)$$

So, we will continue with the linear harmonic oscillator, the simple harmonic oscillator. And we realised that the equation to be solved given the Hamiltonian H is p^2 by $2m$ plus $\frac{1}{2} m \omega^2 x^2$. This is the Hamiltonian and p is to be written as $-\frac{i\hbar}{2m} \frac{d}{dx}$ in the position representation. The equation itself is $H\psi = E\psi$ and that was the time independent Schrodinger equation. And therefore, we had $-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} + \frac{1}{2} m \omega^2 x^2 \psi = E\psi$.

Of course, we realised that there was a part in general which was a function of time and that was not the time independent Schrodinger equation. We have taken these Schrodinger equation and written the wave function as $\psi(x)\chi(t)$ and then of course, this was the part that depends on x and $\chi(t)$ itself had a solution E to the $-\frac{i\hbar}{2m} \frac{d}{dt} \chi = E\chi$ and that is how you define a stationary state. Because, then the expectation values do not change in time and $|\psi|^2$ again does not change in time and so on.

So, we are really looking at solutions to the stationary state wave function in the position representation. And, since we have already worked out the harmonic oscillator problem using the abstract operator method a and a^\dagger and the commutation algebra commutator $[a, a^\dagger] = \text{identity}$. We can now do it in the position representation draw parallels between what we got in the abstract operator method and what we will be getting here in terms of the Eigen values and Eigen functions.

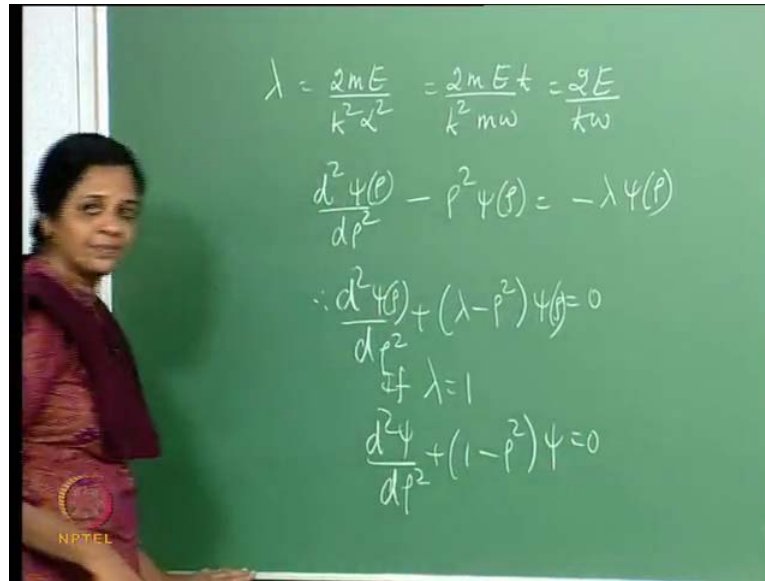

(Refer Slide Time: 02:53)

$$\frac{d^2 \psi(x)}{dx^2} - \frac{m \omega^2 x^2}{\hbar^2} \psi(x) = -\frac{2mE}{\hbar^2} \psi(x)$$
$$\alpha = \sqrt{\frac{m\omega}{\hbar}} \left[\frac{1}{L} \right]$$
$$\frac{d^2 \psi(x)}{dx^2} - \alpha^4 x^2 \psi(x) = -\frac{2mE}{\hbar^2} \psi(x)$$
$$\rho = \alpha x$$
$$\frac{d^2 \psi(\rho)}{d\rho^2} - \rho^2 \psi(\rho) = -\frac{2mE}{\hbar^2 \alpha^2} \psi(\rho)$$

So, we got to a point where I wanted to write this in a more convenient form and therefore, we had $d^2 \psi$ by dx^2 if I suppress the index x , minus m square ω square x square by \hbar cross square ψ of x is minus $2mE$ by \hbar cross square ψ of x . Then I said, let us define α as root of $m \omega$ by \hbar cross and then indeed this becomes $d^2 \psi$ by dx^2 minus α to the 4 x square ψ of x is minus $2mE$ by \hbar cross square ψ of x . Now, we would like to work in terms of dimensionless quantities.

So, I can identify a length scale in this problem. You see this object has dimensions of inverse length that is the dimension. And therefore, if I define an object ρ which is αx , ρ is a dimensionless quantity and then we can recast this equation in terms of ρ for $d^2 \psi$ by dx^2 would become α square $d^2 \psi$ of ρ now by $d\rho$ square minus α to the 4 x square. But then you see if I bring down this α square I get a minus ρ square here. ψ of x is minus $2mE$ by \hbar cross square α square ψ of x . This object $2mE$ by \hbar cross square α square is again a dimensionless quantity.

(Refer Slide Time: 04:48)

$$\lambda = \frac{2mE}{\hbar^2 \alpha^2} = \frac{2mE \hbar}{\hbar^2 m \omega} = \frac{2E}{\hbar \omega}$$
$$\frac{d^2 \psi(\rho)}{d\rho^2} - \rho^2 \psi(\rho) = -\lambda \psi(\rho)$$
$$\therefore \frac{d^2 \psi(\rho)}{d\rho^2} + (\lambda - \rho^2) \psi(\rho) = 0$$
$$\text{If } \lambda = 1$$
$$\frac{d^2 \psi}{d\rho^2} + (1 - \rho^2) \psi = 0$$

I define lambda as $2mE$ by \hbar cross square alpha square. And since alpha was root of $m\omega$ by \hbar cross and therefore, I have an $m\omega$ by \hbar cross here and so this quantity is $2E$ by \hbar cross ω . And that is very nice, because now I have an equation in terms of objects which do not have dimensions. I will comment on this shortly, but I now have $d^2 \psi$ of ρ by $d\rho$ square minus ρ square ψ of ρ is minus lambda ψ of ρ and therefore, I have $d^2 \psi$ by $d\rho$ square plus lambda minus ρ square ψ of ρ equals 0. What is it that we did in the abstract operator formalism? Which was the parallel of what I have done now?

I have now written things in terms of dimensionless quantities. I have introduced a ρ which is dimensionless because alpha had the dimensions of the inverse length and therefore, αx was dimensionless. The equation itself is cast in terms of dimensionless quantities like ρ and lambda.

(Refer Slide Time: 06:21)

Now, you will recall that when we did the abstract operator method in terms of a and a^\dagger , the ladder operators. We said that x was $\sqrt{\frac{\hbar}{m\omega}}$ times $(a + a^\dagger)$ and p was $\sqrt{m\hbar\omega}$ times $(a - a^\dagger)/i$. This has dimensions of length and this has dimensions of momentum. And therefore, a and a^\dagger themselves were dimensionless quantities.

So, when we worked in the abstract operator formalism. We worked with a and a^\dagger and wrote the Hamiltonian as $(a^\dagger a + \frac{1}{2}) \hbar\omega$ and then when I have an equation like $H|n\rangle = E_n|n\rangle$, where n is the state of the oscillator and E_n is the corresponding energy Eigen value. That is the same as saying $(a^\dagger a + \frac{1}{2}) \hbar\omega$ acting on the state n is $E_n|n\rangle$. That equation again is in terms of objects which are dimensionless, a and a^\dagger which are dimensionless quantities. I have scaled out an $\hbar\omega$.

So, I might as well just pull that out and say $a^\dagger a|n\rangle = n|n\rangle$ in units of $\hbar\omega$ and if I forget the half as well for the moment. I have $a^\dagger a|n\rangle = n|n\rangle$ where I realise that E_n is $n + \frac{1}{2}$ $\hbar\omega$ where n is an integer and since I have removed the half $\hbar\omega$ I have this. So, you see this equation that we wrote when we worked out the harmonic oscillator problem using the abstract operator method was an equation in terms of dimensionless quantities. Scaled out the $\hbar\omega$.

cross omega wrote a and a dagger in terms of x and p such that they were dimensionless and then you have this equation.

(Refer Slide Time: 04:48) The analogue of that is precisely this. Except, that I have written it in the position representation and therefore, I have d by d rho and so on occurring here and rho square and so on. But, the whole thing has been recast in terms of dimensionless quantities. So, it is like writing this equation in the position representation and that is what I have done. So, I have psi of rho here. Now, when I solve this equation, I will 1st try to find out if I have any solutions for specific values of lambda and that gives me a handle on solving this equation.

(Refer Slide Time: 04:48) So, for instance if lambda is 1 then d 2 psi by d rho square plus 1 minus rho square psi equals 0, but you see an equation of this form can be factored and written in a different manner all together.

(Refer Slide Time: 09:28)

$$\frac{d^2 \psi}{d\rho^2} + (1 - \rho^2) \psi = 0$$

$$\left(\frac{d}{d\rho} - \rho\right) \left(\frac{d}{d\rho} + \rho\right) \psi = 0$$

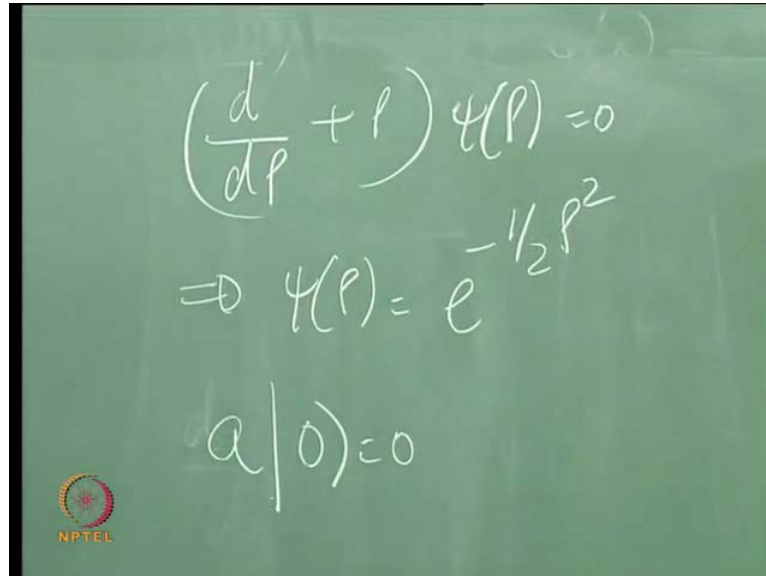

$$\frac{d^2 \psi}{d\rho^2} - \rho \frac{d\psi}{d\rho} + \frac{d}{d\rho}(\rho \psi)$$

$$= \frac{d^2 \psi}{d\rho^2} - \rho \frac{d\psi}{d\rho} + \frac{\rho d\psi}{d\rho} + \psi - \rho^2 \psi$$

I have the equation d 2 psi by d rho square plus 1 minus rho square psi equals 0 and that can be written as d by d rho minus rho d by d rho plus rho psi equals 0. Because, this is just d 2 by d rho square psi, minus rho d psi by d rho plus d by d rho of anything that comes after that so, that is the same as d 2 psi by d rho square minus rho d psi by d rho plus rho d psi by d rho and that cancels out plus psi. And, then I have a minus rho square psi so, that gives me a plus1 minus rho square so, which is what I have here. Therefore, the solution of this equation could well be got from this d by d rho plus rho psi equals 0,

but that solution is obvious if $\frac{d}{d\rho} \psi + \rho \psi = 0$ then that implies that ψ is a Gaussian in ρ .

(Refer Slide Time: 10:44)

$$\left(\frac{d}{dp} + p\right) \psi(p) = 0$$
$$\Rightarrow \psi(p) = e^{-\frac{1}{2}p^2}$$
$$a|0\rangle = 0$$

So, $\frac{d}{d\rho} \psi + \rho \psi = 0$ implies ψ of ρ is e to the minus half ρ square and therefore, that is also a solution of this equation. (Refer Slide Time: 09:28) Since, ψ is a Gaussian and it satisfies this 1st order equation it also satisfies that equation. So, I have a definite solution for $\lambda = 1$, but I know from whatever I have learnt using the abstract operator method that there is a Gaussian solution for the equation a on ket 0 is 0 . You see then we wrote a in terms of x and p , wrote p in the position representation as $-i\hbar \frac{d}{dx}$ and then we got the Gaussian solution, (Refer Slide Time: 06:21) because if I had started there and I had substituted for a , here from this if I solve for a , I simply have $\sqrt{2x}$.

(Refer Slide Time: 12:03)

Let us write down a in terms of x and p . So, I have $\sqrt{2} x$ equals \sqrt{h} cross by $m\omega a + a^\dagger$ and therefore, I have $\sqrt{2} m\omega$ by \sqrt{h} cross x is equal to $a + a^\dagger$. Then, I have an $i p$ again with the $\sqrt{2}$ and on this side I had a $\sqrt{m\omega}$ cross h and therefore, $\sqrt{2} h$ cross $i p$ is a $-a^\dagger$ which gives me a . I can solve for a and I have a is equal to $\sqrt{m\omega}$ by h cross x plus $i p$ by $\sqrt{m\omega}$ cross h . But that was $2a$ and therefore, I have all this divided by 2. So, I have a is equal to $\frac{1}{\sqrt{2}}$ times this object and that is fine because I have again made it dimensionless, apart from the $\frac{1}{\sqrt{2}}$ which I need to put in.

(Refer Slide Time: 13:24)

Now, in the position representation how does this equation look a on ket 0 is equal to 0 looks like this. In the position representation let me write this as ψ_0 of x and a itself can be written in terms of x so, essentially I am trying to say that $\sqrt{m\omega}$ by \hbar cross x plus i $\sqrt{m\omega}$ by \hbar cross acting on ψ_0 of x is 0, but $\sqrt{m\omega}$ by \hbar cross is α . So, I have αx plus i by $\sqrt{m\omega}$ by \hbar cross p is minus i \hbar cross d by $d x$ ψ_0 of x equals 0. So, I have αx plus $\sqrt{\hbar}$ cross by $m\omega$ d by $d x$ ψ_0 of x equals 0 that is the same as saying that gave me an α down stairs. So, 1 by αd by $d x$ plus αx ψ_0 of x equals 0 in terms of ρ which is αx that is simply d by $d\rho$ plus ρ ψ_0 of x equals 0, which is exactly what I have here. (Refer Slide Time: 12:03)

So, it is good to draw a parallel and understand how exactly the abstract operator method when written in the position representation will give me this. I started with writing a ket 0 is 0, but if a is written in terms of x and p and p itself is minus i \hbar cross d by $d x$. I simply get that equation where the solution which is a Gaussian solution. So, that is one thing that I have learnt that for a specific value of λ , λ is equal to 1 the solution is Gaussian. (Refer Slide Time: 09:05) And, then by inspection I see the following: Go back to the general equation. Let me look at the asymptotic form of ψ of ρ , because I know that it has to satisfy boundary conditions. The wave function has to vanish sufficiently fast, has to go sufficiently fast to 0 at spatial infinity that is as ρ goes to plus minus infinity.

(Refer Slide Time: 16:01)

But when rho goes to plus minus infinity this object over powers this and really the value of lambda becomes immaterial. So, in order to study asymptotic behaviour that is as rho goes to plus minus infinity I might well take lambda to be 1 and if I did that I can see that psi of rho should go as e to the minus rho square by 2. Apart from other functions of rho, I will call it u of rho. The dominant behaviour for rho going to large values is E to the minus rho square by 2, goes as E to the minus rho square by 2 and that is all that I needed to know. Now, I can substitute this solution for psi. Recast the differential equation as a differential equation for u, find out u and then I know the full solution, the wave function for the simple harmonic oscillator in the position representation.

(Refer Slide Time: 17:13)

$$\psi(\rho) = e^{-\rho^2/2} u(\rho)$$

$$\frac{d\psi}{d\rho} = u'(\rho) e^{-\rho^2/2} - \rho e^{-\rho^2/2} u(\rho)$$

$$\frac{d^2\psi}{d\rho^2} = u''(\rho) e^{-\rho^2/2} - \rho u'(\rho) e^{-\rho^2/2} - e^{-\rho^2/2} u(\rho) + \rho^2 e^{-\rho^2/2} u(\rho)$$

$$e^{-\rho^2/2} \left[u''(\rho) - 2\rho u'(\rho) + (\lambda - 1)u(\rho) \right] = 0$$

So, that means the following. Let me write psi of rho as e to the minus rho square by 2 u of rho. So, that means d psi by d rho is u prime of rho 1st derivative of u with respect to rho that is psi prime, but I need psi double prime of rho that is the u double prime of rho. I am now going to have a 2nd order equation in u that is what I have from the 1st term. So, this is what I have for d 2 psi by d rho square and then I substitute it back there.

(Refer Slide Time: 16:01) I am going to have an equation which involves both the u double prime and u prime. I have a minus rho e to the minus rho square by 2 u prime of rho and the same thing out here. So, that gives me a minus 2 rho and therefore, I have the equation itself becomes d 2 psi by d rho square gives me u double prime of rho. I am going to pull out an e to the minus rho square by 2. That is the common thing in all of

them and the asymptotics are dictated by $e^{-\rho^2/2}$. So, that is $u''(\rho) - 2\rho u'(\rho) + (\lambda - 1)u(\rho) = 0$. So, I have taken care of these terms.

And then I have $e^{-\rho^2/2} u(\rho)$ (Refer Slide Time: 16:01) and then I have $e^{-\rho^2/2} u(\rho)$. So, there is a cancellation there and then of course, I have λ so, I have $\lambda - 1$ of ρ and I have pulled out an $e^{-\rho^2/2}$ therefore, I have a $\lambda u(\rho)$ that is there. So, I have already taken care of all these terms except this one which is a $-u(\rho)$. So, this object is equal to 0.

(Refer Slide Time: 19:52)

So, let me write this in a convenient fashion. I have $u''(\rho) - 2\rho u'(\rho) + (\lambda - 1)u(\rho) = 0$. So, this is the equation for u 2nd order equation which needs to be solved. Once, I solve for u I can put that back in $\psi(\rho)$ just multiply it with the Gaussian $e^{-\rho^2/2}$ normalise it suitably so, that the wave function obeys the probabilistic interpretation. It is normalised to unity and then I have my answer.

But to solve this equation, I will use the fact that $u(\rho)$. We are now working in function space I will use the fact that $u(\rho)$ can be expanded in terms of polynomials of ρ , I can write it as a polynomial of ρ . Therefore, $u(\rho)$ let me try this solution it is a summation over $C_s \rho^s$ to the power of s . Again, I am interested in the asymptotic behaviour so, definitely I need to worry about s taking large values and s could perhaps

take all values. So, let me say s starts from ν $C_s \rho$ to the power of s some value ν does not matter the small values, I am worried about the asymptotic value. So, let me substitute that there and therefore, I have summation over s C_s . So, u prime of ρ is summation over s $C_s s \rho$ to the s minus 1 which gives me u double prime of ρ is equal to summation over s $C_s s$ times s minus 1 ρ to the s minus 2.

(Refer Slide Time: 21:46)

Now, substitute this I will keep this for later perhaps. So, when I substitute this back I have summation over s $C_s s$ times s minus 1 ρ to the s minus 2. That is what I have for u double prime minus 2 ρ u prime u prime is simply summation over s $C_s s$ times ρ to the s minus 1 plus λ minus 1 u that is equal to 0. Now, here if indeed this should give me 0 it is clear that the coefficients corresponding to every power of ρ should vanish. So, let us compare let us write down the coefficient of ρ to the power of s so, for that let me redo the 1st term. Call s minus 2 as p so it is summation over p suitable summation I am only interested in the asymptotic value so, when s goes to infinity p also goes all the way to infinity.

So, s is p plus 2 so s minus 1 is p plus 1 ρ to the power of p that is the 1st term and I can go back to calling p as s because that summed over, that is just the dummy index. That is my 1st term minus 2 summation over s $C_s s \rho$ to the power of s so, I am just trying to pullout coefficients of ρ to the s plus λ minus 1 summation over s $C_s s \rho$ to the s is 0. And therefore, I have C_{s+2} for any s , C_{s+2} times s plus 2 s

plus 1 is equal to $2Cs + \lambda - 1$. Therefore, $Cs + 2$ by Cs is $2 + \frac{\lambda - 1}{s}$. Now this is a good thing to know because we are interested in what happens for large values of s . The asymptotic behaviour is going to be dictated by this ratio and one wants to see if the series converges at all.

So, let us look at this ratio. For large s this ratio goes as $2/s$ because I have a $2s$ that is negligible compared to that for large s and here I have an s^2 that is a leading term and therefore, I get an s by s^2 so, $1/s$. So, for large s this goes as $2/s$, but I know the another series. I am now trying to find out the solution for u of ρ as a function of ρ . I know of a series which for large s has this asymptotic behaviour and that is unfortunately the series solution for $e^{-\rho^2}$.

(Refer Slide Time: 25:29)

$$\frac{d^2 \psi}{d\rho^2} + (\lambda - \rho^2)\psi = 0, \quad \lambda = \frac{2E}{\hbar\omega}, \quad \rho = \alpha x, \quad \alpha = \sqrt{\frac{m\omega}{\hbar}}$$

If I expand $e^{-\rho^2}$ so, maybe it is good to put down this equation somewhere $d^2 \psi / d\rho^2 + \lambda - \rho^2 \psi = 0$ and $\lambda = 2E / \hbar\omega$ and $\rho = \alpha x$. α itself was $\sqrt{m\omega / \hbar}$ so, there we are.

(Refer Slide Time: 26:56)

So, if you look at the series e to the ρ square and, let us write this as summation over c as ρ to the power of s . You find that for large s , it goes as 1 by s and that is very unfortunate as it stands because that is like telling me that u of ρ is essentially e to the ρ square and therefore, ψ of ρ is e to the ρ square times e to the minus ρ square by 2 , which I guessed from the asymptotic form when λ was 1 and this is therefore, e to the ρ square by 2 which is unfortunate. Because for large ρ it blows up but I want ψ of ρ to go to 0 as ρ goes to infinity.

(Refer Slide Time: 21:46) So, I cannot let terms for large s survive in the series if at all I hope to get a solution. So, the only way to handle this is if the series truncates at some point so, that the coefficients corresponding to large s simply do not contribute. (Refer Slide Time: 19:52) Some value of s where the series truncates and therefore, the summation over s does not go all the way to infinity, but get stops somewhere at a lower value, the finite value. And if that happens then clearly I do not have to worry about the asymptotic behaviour and predict that to be e to the ρ square. So, let us see how exactly this series will truncate. I do not want that. So, one way of solving the problem is to look out if the series truncates somewhere.

(Refer Slide Time: 27:47)

And that is possible because if 2 s is equal to lambda minus 1.

(Refer Slide Time: 28:00)

This is 2 s minus lambda minus 1 here. If 2 s is equal to lambda minus 1 and then I know that the series truncates. But, since s is an integer lambda must be equal to 2 n plus 1 where n is an positive integer and then when s is equal to n the series truncates. So, the summation over s goes from the lower value whatever, it is all the way to n where lambda is 2 n plus 1 where n is a positive integer.

So, that is a possible way of handling this problem and indeed that is a correct way of doing it, but if lambda is equal to 2 n plus 1 go back to the definition of E, E is h cross omega by 2 times lambda. So, E is n plus half h cross omega. So, you see this is very intimately connected with each other. The fact that the asymptotic behaviour of psi should be admissible, the fact that psi should go to 0 for large values of rho and therefore x, puts a constraint on lambda because the series has to truncate and that in turn tells me, what the Eigen values are.

So, the Eigen values are of the form n plus half h cross omega and in principle n can be zero 1 2 3 anything And when n is equal to 0 it tells me that lambda is equal to 1 and that is the lowest value that n can take, because s has to take positive values. So, lambda is equally to 1 really corresponds to the ground state of the oscillator and indeed we saw that the ground state of the oscillator, the wave function in the position representation is a Gaussian wave function and that is how things get linked up with each other.

In any case going back here suppose, there is some value of n where this series truncates that is very nice because then u of rho is simply summation over s all the way to n C s rho to the power of s and that is it. So, C n is not equal to 0, but c n plus 1 etcetera are 0. It is a finite series, now look back at this and if I do that: What kind of equation do I have here? This equation is essentially the same as the equation satisfied by the Hermite polynomials because the equation for the Hermite polynomials is like this.

(Refer Slide Time: 31:28)

$$u''(\rho) - 2\rho u'(\rho) + (\lambda - 1)u(\rho) = 0$$

$$H_n''(\rho) - 2\rho H_n'(\rho) + 2n H_n(\rho) = 0$$

Hermite differential eqn.
 $H_n(\rho)$: polynomial fn. of ρ

NPTEL

Suppose, H_n of ρ is a Hermite polynomials the solution of the equation H_n double prime of ρ minus 2ρ H_n prime of ρ plus $2n$ H_n of ρ equals 0 it is the Hermite differential equation. These are polynomials in ρ ; H_n of ρ is a polynomial in ρ . I briefly mentioned the properties of H_n of ρ in an earlier lecture said there in function space they could form a basis. The function space that we are considering here for the harmonic oscillator problem is clearly $-\infty$ to ∞ because ρ takes values $-\infty$ to ∞ so, the solution of u of ρ is essentially H_n of ρ .

(Refer Slide Time: 32:44)

$$u_n''(\rho) - 2\rho u_n'(\rho) + (\lambda - 1)u_n(\rho) = 0$$

\swarrow
 $(2n+1)$

$$u_n(\rho) = N_n H_n(\rho)$$

Apart from some normalisation constant and therefore, u of ρ is some normalisation H_n of ρ and therefore, I would like to call this u_n of ρ . λ itself is $2n + 1$ and therefore, the n is brought in here.

(Refer Slide Time: 33:11)

So, we could well write u_n of ρ minus $2\rho u_n$ prime of ρ and a u_n of ρ there, this λ . So, that is what I have. So, this is some normalisation which I will call it N . H_n of ρ and clearly the normalisation would have 1 by $\sqrt{\pi^{1/2} 2^n n!}$ to the power n factorial to the half. From the orthonormality property for H_n which I just now wrote and therefore, this is what I should be having for u_n of ρ . I need u_n of x and since ρ is equal to αx , u_n of x is α by $\sqrt{\pi^{1/2} 2^n n!}$ to the power of n factorial to the power of half H_n of x so, this is what I have. And this is normalised to unity the u_n 's form an orthonormal basis set of functions, but now going back to ψ I now write ψ_n of x because for a given value of n and therefore, λ and therefore, e I have a certain wave function and that is given by this object u_n of ρ which is essentially H_n .

So, let me not write the normalisation. It is some normalisation N , H_n of x times the Gaussian e to the minus x square by 2 . The Gaussian takes care of the fact that the wave function goes to 0 sufficiently fast at space infinity. The H_n of x themselves arose, because the series had to be truncated in order that the wave function was an admissible wave function. Not every wave function which is square integrable can be a solution to our problem its only those wave functions which satisfy the boundary conditions imposed by the physical requirement of the probabilistic interpretation. That wave function must be normalised to 1 and therefore, the probability of seeing the system in the given region of space is 1 . It is that, that is going to bring out an H_n of x here and

therefore, I have Eigen functions of the oscillator given by ψ_n of x with the energy Eigen values given by n plus half $\hbar \omega$.

So, in this method of working out Eigen values and Eigen functions there are some crucial points which are worth noting and which we will be using in subsequent problems that we will consider. Wherever, possible we will go to dimensionless variables. In this case we went to ρ and λ , where ρ itself do not have the dimensions of length x ((Refer Time: 36:07)) and α has dimensions of $1/\text{length}$ and therefore, ρ was dimensionless. Similarly, λ did not have dimensions because λ was $2e/\hbar \omega$.

So, we will do that always and that as I said connects up with the abstract operator method, because we wrote that in terms of a 's and a^\dagger 's which were dimensionless objects. In fact I had explicitly illustrated that a on ket 0 is equal to 0 really turned out to be the differential equation with λ set equal to 1 here in the case of the position representation. These are the wave functions, but I know that these wave functions must have definite parity.

I know this because of an earlier argument that I had given that the Hamiltonian for the harmonic oscillator for the 1 dimensional oscillator commutes with the parity operator and from that I had earlier shown that the wave functions would have definite parity. The Eigen states of the Hamiltonian would have definite parity either positive parity or negative parity, and that there is a complete set of common Eigen states of the parity operator and the Hamiltonian.

(Refer Slide Time: 37:42)

Now, that you can verify right here. Because the H_n s can be written in the following fashion: H_0 of x is 1, H_1 of x is $2x$, H_2 of x is $4x^2 - 2$. So, you see this has odd parity, this has even parity, that has even parity and so on e to the minus x square by 2 anyway is in even parity state when s goes to minus x e to the minus x square by 2 does not change sign and therefore, these wave functions have a definite parity. It is clear that ψ_0 of x , ψ_0 of x , ψ_2 of x and so on are even parity states that means ψ_0 of minus x is plus ψ_0 of x and so on. And ψ_1 of x , ψ_3 of x , ψ_5 of x are odd parity states that means ψ_1 of minus x is minus ψ_1 of x and so on.

(Refer Slide Time: 33:11) This property is reflected by the fact that the ψ_n of x is essentially H_n of x and the H_n 's themselves have even and odd parity like I have shown here. Now, if you look at the wave function and have a schematic plot of these wave functions as a function of x you can schematically see the following.

(Refer Slide Time: 39:20)

So, if you take ψ_0 of x remember that this is the same in my notation as $x|0\rangle$, where a $|0\rangle$ ket was 0. This written in the position representation is ψ_0 of x and if I plot ψ_0 of x versus x , get a Gaussian in x centred at x is equal to 0. Then, if you look at ψ_1 of x and ψ_1 of x is $x|1\rangle$ in my notation when n takes the value 1. Goes to 0 at plus infinity and minus infinity, but that is antisymmetric function of x and therefore, you can see that it has odd parity.

Look at the number of times it cuts the axis. ψ_0 of x does not cut the axis; it just goes all the way to plus minus infinity. There is no finite value of x where the wave function vanishes as far as ψ_0 of x is concerned. As far as ψ_1 of x is concerned it has one point where it vanishes it is a node. A node is a point where the wave function vanishes.

(Refer Slide Time: 40:57)

Now, look at ψ_2 of x that is an even parity state. The wave function goes to 0 at space infinity. It is a symmetric wave function cuts the axis at 2 points. These are the nodes. This in my notation is x_n is equal to 2, quantum optics I would call it the 2 photon state I have written the 2 photon state in the x representation if I were talking in the language of quantum optics. In the case of simple harmonic oscillator I would simply say that it is the 2nd excited state of the oscillator so, we have this.

(Refer Slide Time: 39:20) Now, the number of nodes is increasing the ground state had 0 nodes, the 1st excited state of the oscillator has 1 node, the 2nd excited state has 2 nodes and so on. And why does the number of nodes increased with energy? Now, that is something that we can see rather easily, because in general the number of nodes would increase with energy for the following reason.

(Refer Slide Time: 42:16)

$$\frac{p^2}{2m}$$

$$\langle E \rangle = \frac{1}{2m} \int (P\psi)^*(P\psi) dx$$

$$= \frac{1}{2m} \int \left(-i\hbar \frac{d\psi}{dx}\right)^* \left(-i\hbar \frac{d\psi}{dx}\right) dx$$

$$\approx \int |\nabla\psi|^2 dx$$

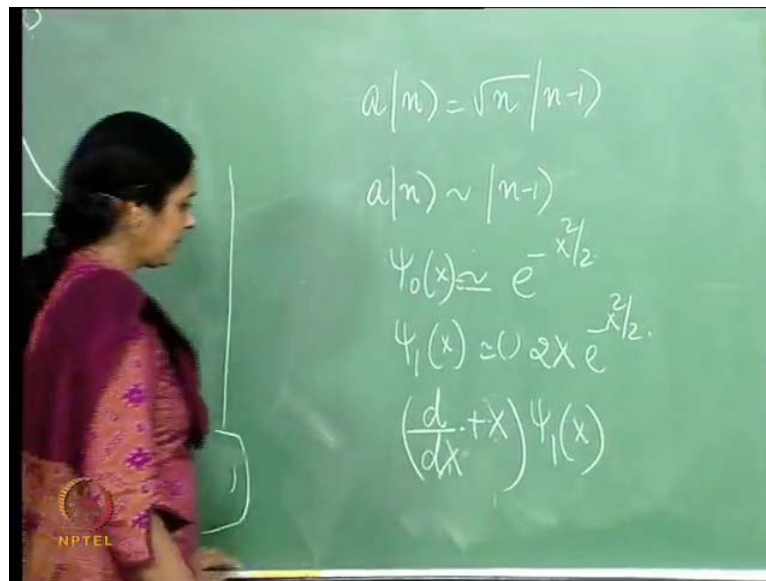

The contribution to the Hamiltonian comes from p square by $2m$ and therefore, I have $P\psi$, $P\psi^*$ I am trying to find out the expectation value of the energy, the contribution from the kinetic energy. Since that had a p square by $2m$ and I can pull out the 1 by $2m$, I would just have $P\psi^* P\psi$ and this is all a function of x and therefore, I have d x . Where, I have ψ of x and p itself is minus $i\hbar$ cross d by d x . So, the expectation value of the energy is integral minus infinity to infinity minus $i\hbar$ cross $d\psi$ by d x star minus $i\hbar$ cross $d\psi$ by d x d x . But apart from constants involves a gradient operator so, that is essentially an integral over $grad \psi$ mod square d x .

And, since the gradient operator adds to the energy the more the gradients, the more the number of times you have to go up and down there is an increase in energy (Refer Slide Time: 40:57) and every time you cross a node you go down go up. Whereas, here (Refer Slide Time: 39:20) that does not happen. Here, you go up once here you go up twice and so on. Therefore, as the number of nodes increases there is no work done. The gradient operator brings in a larger contribution and therefore, and as the energy levels increase

you find that the number of nodes increases. In the case of the oscillator problem the number of nodes increases by 1.

(Refer Slide Time: 40:57) The n -th excited state of the oscillator has n nodes. That means the wave function cuts the x axis n times and that is what you see here. There is a last point that I want to make before I close this lecture to connect up the abstract operator method that we had with whatever we have written here.

(Refer Slide Time: 44:35)

We know that in the abstract operator method we had shown this, barring constants it is clear that a on ket n is essentially ket n minus 1 so, let us see if this is really true. I know that ψ_0 of x that corresponds to ket 0 is e to the minus x square by 2 it is a Gaussian and then there is a normalisation which I will forget for the moment but it is essentially a Gaussian. And then ψ_1 of x is the Hermite polynomial H_1 of x which is $2x$ e to the minus x square by 2. That is again apart from normalisations.

So, let us see if a in the position representation acting on ψ_1 really gets it to ψ_0 of x . So, a you will recall is d by d rho plus rho and this is supposed to act on this object so, let us worry about d by d x plus x acting on ψ_1 of x . Let us evaluate this.

(Refer Slide Time: 46:03)

The image shows a chalkboard with the following handwritten equations:

$$\left(\frac{d}{dx} + x\right) \psi_1(x) = \frac{d}{dx} \left(x e^{-x^2/2}\right) + x^2 e^{-x^2/2}$$

$$= e^{-x^2/2} - x^2 e^{-x^2/2} + x^2 e^{-x^2/2}$$

$$a|1\rangle \approx |0\rangle$$

In the bottom right corner, there is a boxed equation for the annihilation operator:

$$a = \frac{1}{\sqrt{2}} \left[\sqrt{\frac{m\omega}{\hbar}} x + i \frac{p}{\sqrt{m\hbar\omega}} \right]$$

The NPTEL logo is visible in the bottom left corner of the chalkboard image.

That is the analogue of a on ket 1. Of course, I am forgetting constants I am just trying to see the general pattern. So that is e to the minus x square by 2 plus minus x square e to the minus x square by 2 plus x square e to the minus x square by 2 and that gives me the Gaussian. So, you see a on ket 1 is essentially ket 0 the essentially because, I have not put down the constants. This is good enough for me to see it. Similarly, if you look at a dagger on ket 0 you can check that that gives me ket 1. In other words, a dagger acting in the position representation acting on e to the minus x square by 2 takes it to $x e$ to the minus x square by 2 and that is what you have plotted here.

(Refer Slide Time: 39:20) This is e to the minus x square by 2 schematically. This is $x e$ to the minus x square by 2 and so on. So, we have checked therefore, that the operator formalism exactly matches with the position representation formalism of the harmonic oscillator problem. Now, it is a matter of convenience. If all we need are the energy Eigen values and the energy Eigen functions we could well work with the operator method provided we are not interested in the position. Provided we are not interested in the manner in which the oscillator oscillates in time, what are the instantaneous values of position? And so on. If that is a matter of interest to us then it is more convenient to write things in terms of the position representation.

Otherwise, all these results could have been got perhaps with lesser work in some sense if we use the abstract operator formalism. And now, we have established that both of

them are equivalent methods of solving the same problem. In the position representation the energy Eigen states of the oscillator. The Hilbert space is separable spaces say the numerable infinity of Eigen states and each one of them happens to be representable essentially as appropriate Hermite polynomials producted with a Gaussian, suitably normalised. That is a wave function in the position representation and the corresponding Eigen values of course, are n plus half h cross ω where n takes value 0, 1, 2, 3, and so on.
