Lecture - 52
Ideal Fermi Gas close to T=0, Chemical Potential and Specific Heat

(Refer Slide Time: 00:24)

Not strictly at T=0 but very close to it.

$\eta = -1$

$$f_m^-(z) = \frac{1}{(m-1)!} \int_0^\infty dx \frac{x^{m-1}}{z^{-1}e^x + 1}$$

$$= \frac{1}{(m-1)!} \left[\frac{1}{z^{-1}e^x + 1} \frac{x^m}{m} \Big|_0^\infty - \int_0^\infty dx \frac{x^m}{m} \frac{d}{dx} \left(\frac{1}{z^{-1}e^x + 1} \right) \right]$$

$$f_m^-(z) = \frac{1}{m!} \int_0^\infty dx x^m \frac{d}{dx} \left(\frac{-1}{z^{-1}e^x + 1} \right)$$

So now, we want to understand that what happens, if we are not strictly at T equal to 0, but very close to it right. So, we start off with the integral that we have defined now it is a fermionic system therefore; we put a minus that says that this is for a fermionic system where eta is equal to minus 1. And this we have defined as m minus 1 factorial, 0 to infinity dx x to the power m minus 1, Z inverse e to the power x plus 1.

The idea is first to integrate by parts, and if I want to integrate by parts so, 1 over Z inverse e to the power x plus 1 and integral of x to the power m minus 1 dx is going to be x to the

power m 0 to infinity and then, I am going to have 0 to infinity dx x to the power m over m . And I am going to have $d dx$ of 1 over Z inverse e to the power x plus 1 right.

So, that this is going to vanish at x equal to 0 this vanishes at x equal to infinity e to the power x diverges so, this 0 in both the limits and my m times m minus 1 factorial is 1 over m factorial integration dx x to the power m $d dx$ of 1 over Z inverse e to the power x plus 1 . So, I have $f m$ minus of Z is equal to this.

(Refer Slide Time: 02:38)

$$\begin{aligned}
 \beta \epsilon &= \beta \mu + t & t &= \beta(\epsilon - \mu) & z^{-1} e^{\beta \mu + t} &= z^{-1} e^{\beta \mu} e^t \\
 x &= \ln z + t & dx &= dt
 \end{aligned}$$

$$\begin{aligned}
 \Gamma_m^{-1}(z) &= \frac{1}{m!} \int_{-\infty}^{\infty} dt (t + \ln z)^m \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right) \\
 &= \frac{1}{m!} \int_{-\infty}^{\infty} dt \sum_{\alpha=0}^{+\infty} \binom{m}{\alpha} t^\alpha (\ln z)^{m-\alpha} \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right) \\
 &= \frac{(\ln z)^m}{m!} \int_{-\infty}^{\infty} dt \sum_{\alpha=0}^{\infty} \frac{m!}{\alpha! (m-\alpha)!} (\ln z)^{-\alpha} t^\alpha \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right)
 \end{aligned}$$

Now, I am very very close to t equal to 0 . So, that we write the $\beta \epsilon$ as $\beta \mu$ plus t and t is $\beta \epsilon$ minus μ . Since, I am really very close to t equal to 0 you see the values of t will run from minus infinity to plus infinity right. So, that X is going to be $\ln Z$ plus t right and dx is going to be dt .

So, that f inverse of z is going to be this is the low temperature expansion we are looking at very close to t equal to 0 minus infinity to plus infinity dt t plus $\ln Z$ raised to the power m , substitute over here and then you have $d dt$ of minus 1 e to the power t plus 1 right.

Z inverse e to the power x is going to be Z is e to the power $\beta \mu$. So, that this is going to x is going to be $\ln z$ plus t so, that you are going to have e to the power $\ln Z$ plus t which is going to be Z inverse times Z plus t , e to the my mistake Z inverse times Z times e to the power t and this is 1 therefore, you have e to the power t plus 1.

Now, this is a binomial expansion, I can do a binomial expansion over here and this expansion is going to be $m C \alpha t$ to the power α $\ln Z$ raised to the power m minus α $d dt$ of minus 1 e to the power t plus 1.

So, that I can take $\ln Z$ raised to the power m divided by m factorial outside and minus infinity to plus infinity dt sum over α equal to 0 to infinity, I will have m factorial, α factorial, m minus α factorial $\ln Z$ raised to the power m minus α and then I am going to have $d dt$ of minus 1 e to the power t plus 1. There is a t to the there is a t to the power α that is missing over here so, we include that.

(Refer Slide Time: 05:56)

$$\begin{aligned}
 g(t) &= t^\alpha \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right) \quad t \rightarrow -t & \overline{g(-t)} &= (-1)^\alpha g(t) \\
 & \alpha \text{ is even} & g(-t) &= g(t) & g(t) & \text{even function.} \\
 & \alpha \text{ is odd} & g(-t) &= -g(t) & g(t) & \text{is odd function.} \\
 & & & & & \\
 & = \frac{(\ln z)^m}{m!} \sum_{\alpha} \frac{m!}{\alpha! (m-\alpha)!} (\ln z)^{-\alpha} \int_{-\infty}^{\infty} dt t^\alpha \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right) \\
 & \int_{-\infty}^{\infty} dt t^\alpha \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right) = 0 \quad \text{when } \alpha \text{ is odd} \\
 & = 2 \int_0^{\infty} dt t^\alpha \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right) \quad \text{when } \alpha \text{ is even.}
 \end{aligned}$$

Now, note that g of t lets call this as t to the power α d dt of $\frac{-1}{e^t + 1}$. If you note this then you will realize that this is going to be g of $-t$ is going to be $\frac{-1}{e^{-t} + 1}$ raised to the power α so, if you substitute t for $-t$ then you are going to get g of $-t$ as g of t .

So if you look at it, then you see that if α is even then g of $-t$ is exactly g of t that means, g of t is an even function. If α is odd g of $-t$ is $-g$ of t so, that g of t is odd function. Now, this we are going to utilize, let us see how we are going to utilize. I can take this integral over here.

So, that I have $(\ln z)^m$ raised to the power m m factorial sum over α m factorial, m factorial, $m - \alpha$ factorial, and then I have $(\ln z)^{-\alpha}$ raised to the power α , I

have integral minus infinity to plus infinity dt t to the power alpha d dt of minus 1 e to the power t plus 1.

Now, this I have just now said that this is going to be an even function, if alpha is even and it is going to be an odd function is alpha is odd. So, that this integral minus infinity to plus infinity dt is going to be t to the power alpha d dt of minus 1 e to the power t plus 1 is going to be 0, when alpha is odd.

And this follows from that the fact that when alpha is odd g t is an odd function, and is going to be integration there is going 2 factor dt t to the power alpha d dt of minus 1 e to the power t plus 1, when alpha is even; good.

(Refer Slide Time: 08:36)

$$\begin{aligned}
 \int_{-\infty}^{\infty} dt t^{\alpha} \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right) &= 0 \quad \text{when } \alpha \text{ is odd} \\
 &= 2 \int_0^{\infty} dt t^{\alpha} \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right) \quad \text{when } \alpha \text{ is even.} \\
 f_m^{-}(z) &= \frac{(h_m z)^m}{m!} \sum_{\alpha}^{\text{even}} \frac{m!}{\alpha! (m-\alpha)!} (h_m z)^{-\alpha} \int_0^{\infty} dt t^{\alpha} \frac{d}{dt} \left(\frac{-1}{e^t + 1} \right) \\
 f_m^{-}(z) &= \int_0^{\infty} dt \frac{t^{m-1}}{e^t + 1}
 \end{aligned}$$

So, therefore, I have f_m minus of Z is going to be \ln of Z raised to the power m ; m factorial, I then have the sum over α but now, α only even values are allowed so, that I have m factorial, α factorial, m minus α factorial. I have $\ln Z$ raised to the power minus α and then, I have a $2 \int_0^\infty dt t^\alpha \frac{d}{dt} (e^{-t+1})$ right.

If you are clever enough then you will see that I can integrate again by parts and I will come up that this integral is going to be $\int_0^\infty dt t^{\alpha-1} e^{-t+1}$, and this is exactly $f_{\alpha-1}$ so, that I have so if you want to recall [FL].

(Refer Slide Time: 10:10)

$$\begin{aligned}
 f_m(z) &= \frac{(z \ln z)^m}{m!} \sum_{\alpha}^{\text{even}} \frac{m!}{\alpha! (m-\alpha)!} (z \ln z)^{-\alpha} \left[2 \int_0^\infty dt t^\alpha \frac{d}{dt} \left(\frac{-1}{e^t+1} \right) \right] \quad \text{when } \alpha \text{ is even.} \\
 &= \frac{(z \ln z)^m}{m!} \sum_{\alpha}^{\text{even}} \frac{m!}{\alpha! (m-\alpha)!} (z \ln z)^{-\alpha} \left[2 \int_0^\infty dt t^\alpha \frac{d}{dt} \left(\frac{-1}{e^t+1} \right) \right] \\
 &= \frac{1}{\alpha!} \int_0^\infty dt t^\alpha \frac{d}{dt} \left(\frac{-1}{e^t+1} \right) \quad f_m(z) = \frac{1}{(m-1)!} \\
 &= \frac{1}{\alpha!} \int_0^\infty dt \frac{t^{\alpha-1}}{e^t+1}
 \end{aligned}$$

So, now I can combine this integral with 1 by α factorial and t to the power α $\frac{d}{dt}$ of minus 1 e to the power t plus 1 . So, that this is 1 over α factorial $\int_0^\infty dt t^{\alpha-1} e^{-t+1}$. So, that this is 1 over α factorial $\int_0^\infty dt t^{\alpha-1} e^{-t+1}$. So, that this is 1 over α factorial $\int_0^\infty dt t^{\alpha-1} e^{-t+1}$. So, that this is 1 over α factorial $\int_0^\infty dt t^{\alpha-1} e^{-t+1}$.

integrate by parts again here and it is going to be t to the power α minus 1 e to the power t plus 1 .

(Refer Slide Time: 10:56)

$$\frac{1}{\alpha!} \int_0^{\infty} dt t^{\alpha} \frac{d}{dt} \left(\frac{-1}{e^t - 1} \right)$$

$$\frac{1}{\alpha!} \left[\frac{-t^{\alpha}}{e^t - 1} \Big|_0^{\infty} - \int_0^{\infty} dt \alpha t^{\alpha-1} \left(\frac{-1}{e^t - 1} \right) \right]$$

$$\frac{1}{(\alpha-1)!} \int_0^{\infty} dt \frac{t^{\alpha-1}}{e^t - 1} = f_{\alpha}^{-}(1)$$

$$f_m^{-}(z) = \frac{(ln z)^m}{m!} \sum_{\alpha}^{even} 2 f_{\alpha}^{-}(1) \frac{m!}{(m-\alpha)!} (ln z)^{-\alpha}$$

So, that you immediately realize that this function if you recall I had this as m minus 1 factorial, to give me 1 over α factorial 0 to infinity dt t to the power α d dt of minus 1 e to the power t plus 1 . I can integrate by parts this one again. So, what happens if I integrate by parts? I can take this as the first function so, that you have t to the power α then integral of dt is gives you minus e to the power t plus 1 0 to infinity.

Then, you have minus dt derivative of this is t to the power α minus 1 and then you have essentially minus 1 of e to the power t plus 1 , this vanishes and you have α minus 1 factorial 0 to t infinity dt t to the power α minus 1 divided by e to the power t plus 1 , strikingly familiar right because, this is f of α minus 1 .

So, that my low temperature expansion becomes $\ln Z$ raised to the power m divided by m factorial, I have sum over α which are even values of α 1 out twice f α minus 1 times m factorial divided by m minus α factorial and then, I have $\ln Z$ raised to the power m minus α right.

(Refer Slide Time: 12:39)

$$\begin{aligned}
 & \int_m^-(z) = \frac{(\ln z)^m}{m!} \sum_{\alpha}^{\text{even}} 2 \int_{\alpha}^-(1) \frac{m!}{(m-\alpha)!} (\ln z)^{-\alpha} \\
 & = \frac{(\ln z)^m}{m!} \left[1 + \frac{\pi^2}{6} m(m-1) (\ln z)^{-2} + \frac{7\pi^4}{360} \frac{m(m-1)(m-2)(m-3)}{(\ln z)^4} + \dots \right] \\
 n & = \frac{g}{\Lambda_T} f_{3/2}^-(z)
 \end{aligned}$$

So, this is the limiting value limit of Z to infinity f m minus of Z , if you take this is the approximation that you get. So, I can now write it down m factorial using the values of f this functions is going to be π^2 over 6 m into m minus 1 , $\ln Z$ minus 2 plus $7 \pi^4$ over 360 m into m minus 1 into m minus 2 into m minus 3 divided by $\ln Z$ raise to the power 4 plus higher order terms; good.

What do I do with it? Well our starting point again is to look at the number density. The number density we know that for a quantum ideal gas is g over λ_T^3 times Z for a fermionic system right, and I am looking at the limit of z to infinity.

(Refer Slide Time: 13:58)

$$= \frac{(\ln z)^m}{m!} \left[1 + \frac{\pi^2}{6} m(m-1) (\ln z)^{-2} + \frac{7\pi^4}{360} \frac{m(m-1)(m-2)(m-3)}{(\ln z)^4} + \dots \right]$$

$$n = \frac{g}{\lambda_T^3} Z^{-1/2} (z)$$

$$\frac{n \lambda_T^3}{g} = \frac{(\ln z)^{3/2}}{(3/2)!} \left[1 + \frac{\pi^2}{6} \frac{3/2 \cdot 1/2}{2} (\ln z)^{-2} + \dots \right]$$

$$\frac{(\beta \epsilon_F)^{3/2}}{1 + \frac{\pi^2}{6} \frac{3/2 \cdot 1/2}{2} (\ln z)^{-2} + \dots}$$

$$\frac{n \lambda_T^3}{g} = \frac{(\ln z)^{3/2}}{(3/2)!} \leftarrow \left(\frac{3}{2}\right)! = \frac{3\sqrt{\pi}}{2}$$

$$\ln z = \beta \epsilon_F$$

$$\ln z = \beta \epsilon_F \left[1 + \frac{\pi^2}{8} \left(\frac{\beta \epsilon_F}{\lambda_T}\right)^2 + \dots \right]^{-2/5}$$

So that means, $n \lambda_T^3$ over g is going to be $\ln Z$ to the power 3 half. So, I am going to have 3 half factorial $1 + \pi^2$ over 6 m into sorry m is 3 half and therefore, I have 3 half into half and I have 1 over $\ln Z$ whole square we will keep it as higher order terms. The lowest correction is when this is equal to this.

So, that I have $n \lambda_T^3$ over g is going to be $\ln Z$ raised to the power 3 half by 3 by 2 factorial, and 3 by 2 factorial you should note is 3 by 2 square root π over 2. So, once you put

in over here and if you compute $\ln Z$ from this term you will see that you are going to get $\ln Z$ is equal to $\beta \epsilon_F$, which is the Fermi energy at 0 temperature.

Then, if I have this I can write down $\ln Z$ invert this over here which is going to be $\beta \epsilon_F$ $1 + \frac{\pi^2}{8} (\beta \epsilon_F)^{-2}$ $\ln Z$ is $\beta \epsilon_F$ to the leading order. So, we will write this as $\frac{K_B T}{\epsilon_F}$ $1 + \frac{\pi^2}{8} (\frac{K_B T}{\epsilon_F})^2 + \dots$ higher order terms raised to the power minus 2 by 3 right. Why is that? Because you see to the leading order I have determined that $\ln Z$ is going to be $\beta \epsilon_F$ so exactly at 0 temperature right, which I also get it by ignoring all the other terms in the series.

Once I have that then essentially I have $\beta \epsilon_F$, raised to the power 3 half if I look at this expression this whole equation I take this whole equation divided by $1 + \frac{\pi^2}{8} (\beta \epsilon_F)^{-2}$ times 3 by 2 times half 1 over $\ln Z$ whole square, but $\ln Z$ is equal to $\beta \epsilon_F$ I am very very close to the 0 temperature.

(Refer Slide Time: 16:37)

$$n = \frac{d}{\lambda_T} \left(\frac{3}{2} \right)^{3/2}$$

$$\frac{(k_B T)^{3/2}}{\beta \epsilon_F} = \left(\frac{k_B T}{\beta \epsilon_F} \right)^{3/2} \frac{n \lambda_T}{j} = \frac{(k_B T)^{3/2}}{(3/2)!} \left(\frac{3}{2} \right)^{3/2} = \frac{3 \sqrt{\pi}}{2}$$

$$\ln Z = \beta \epsilon_F$$

$$\ln Z = \beta \epsilon_F \left[1 + \frac{\pi^2}{8} \left(\frac{k_B T}{\epsilon_F} \right)^2 + \dots \right]^{-3/2}$$

$$\ln Z = \beta \epsilon_F \left[1 - \frac{2}{3} \cdot \frac{\pi^2}{8} \left(\frac{k_B T}{\epsilon_F} \right)^2 + \dots \right]$$

$$= \beta \epsilon_F \left[1 - \frac{\pi^2}{12} \left(\frac{k_B T}{\epsilon_F} \right)^2 + \dots \right]$$

So, here I am going to write down beta epsilon F 1 by beta epsilon F whole square which is nothing but K B T over epsilon F whole square plus higher order terms, and this is ln Z raised to the power 3 half right.

So, this then leads me to this equation and you see that ln Z is going to be beta epsilon F 1 minus 2 by 3 times pi square over 8 K B T for epsilon F whole square plus higher order terms which is going to be beta epsilon F 1 minus pi square over 12 K B T over epsilon F whole square plus higher order term.

(Refer Slide Time: 17:35)

$$\mu(T) = \epsilon_F \left[1 - \frac{\pi^2}{12} \left(\frac{k_B T}{\epsilon_F} \right)^2 + \dots \right]$$

$\frac{\epsilon_F}{k_B} = T_F$

Small temperature - $T < \frac{\epsilon_F}{k_B}$ $\mu > 0$
 $\mu < 0$

$T \sim \frac{\epsilon_F}{k_B} = T_F$

So, that the chemical potential very close to 0 not exactly at 0, since this is going to be beta mu is going to be epsilon F 1 minus pi square over 12 K B T over epsilon F whole square plus this. So, that as you go away from zero temperature you see the chemical potential decreases with as a quadratic in temperature.

So, we looked at the chemical potential as a function of temperature and you realize from looking at this equation that for small temperatures, which are less than epsilon F over K B can the chemical potential is positive. So, mu is greater than 0. This particular quantity epsilon F over K B is called the Fermi temperature T F right.

In contrast for high temperatures mu is less than 0 mu becomes the chemical potential is negative, and the zero crossing happens at temperature which is of the order of epsilon over K

B that is equal to your T F of the order it does not exactly happen that T F, but it happens of the order of T F.

(Refer Slide Time: 19:10)

$$\begin{aligned}
 \beta P \eta &= \frac{g}{\lambda_T} f_{5/2}^-(z) & f_{5/2}^-(z) &= \frac{(ln z)^{5/2}}{(5/2)!} \left[1 + \frac{\pi^2}{6} \frac{5}{2} \frac{3}{2} (ln z)^{-2} + \dots \right] \\
 &= \frac{g}{\lambda_T} \frac{8}{15\sqrt{\pi}} (ln z)^{5/2} \left[1 + \frac{5\pi^2}{8} (ln z)^{-2} + \dots \right] & \beta \epsilon_F & \\
 (ln z)^{5/2} &= (\beta \epsilon_F)^{5/2} \left[1 - \frac{\pi^2}{12} \left(\frac{T}{T_F} \right)^2 + \dots \right] & & \left[1 + \frac{5\pi^2}{8} n^2 \left(\frac{T}{T_F} \right)^2 + \dots \right]
 \end{aligned}$$

Now, our next interest lies in looking at the pressure. So, I know that beta P eta is g over lambda T f 5 by 2 minus of Z, and I am looking at the low temperature expansion and therefore, I am interested in the expansion that we did a little while ago right, this is the one.

So, we will only keep up to ln Z up to this order and therefore, f of 5 by 2 minus of Z is ln Z raised to the power 5 by 2 divided by 5 by 2 factorial times 1 plus pi square over 6 m m minus 1 is 3 by 2 m is 5 by 2 here, and I have ln Z raised to the power minus 2 plus higher order terms.

So, that this expression is g over λ_T 8 by 15 the 5 by 2 factorial square root π and then I have $\ln Z$ raised to the power 5 by 2 I have 1 plus 5 π square over 8 $\ln Z$ raised to the power minus 2 plus higher order. All I have to do now is to substitute $\ln Z$ from the here.

So, let us do that. So, $\ln Z$ raised to the power 5 by 2 is $\beta \epsilon_F$ raised to the power 5 by 2 and then I have this term, which is raised to the power 5 by 2 that is 1 minus π square over 12 . I have $K_B T$ over ϵ_F whole square which we will write down as T over T_F whole square plus higher order terms raised to the power 5 by 2 .

And in this term I am going to replace since I am looking at the leading order correction I am just going to replace this $\ln Z$ as $\beta \epsilon_F$ which is T over T_F raised to the power square plus higher order terms sorry ok, this discussion comes little later.

(Refer Slide Time: 21:55)

$$\beta p_{\eta} = \frac{g}{\lambda_T} f_{5/2}^{-}(z) \quad f_{5/2}^{-}(z) = \frac{(ln z)^{-5/2}}{(5/2)!} \left[1 + \frac{\pi^2}{6} \frac{5}{2} \frac{3}{2} (ln z)^{-2} + \dots \right]$$

$$= \frac{g}{\lambda_T} \frac{8}{15\sqrt{\pi}} (ln z)^{5/2} \left[1 + \frac{5\pi^2}{8} (ln z)^{-2} + \dots \right] \rightarrow \beta \epsilon_F$$

$$(ln z)^{5/2} = (\beta \epsilon_F)^{5/2} \left[1 - \frac{\pi^2}{12} \left(\frac{T}{T_F} \right)^2 + \dots \right]$$

$$\beta p_{\eta} = \frac{g}{\lambda_T} \frac{8}{15\sqrt{\pi}} (\beta \epsilon_F)^{5/2} \left[1 - \frac{5\pi^2}{2} \frac{\pi^2}{12} \left(\frac{T}{T_F} \right)^2 + \dots \right] \left[1 + \frac{5}{8} \pi^2 \left(\frac{T}{T_F} \right)^2 + \dots \right]$$

So, here just I am going to replace this by beta epsilon F. So, that beta times P eta the pressure becomes g over lambda T 8 over 15 square root pi ln Z 5 by 2 raised to the power 5 by 2 is beta epsilon F raised to the power 5 by 2, then I have 1 minus pi square over 12.

Since, this bracketed quantity is raised to the power 5 by 12, I will use a binomial expansion to write it down like this way and then I have T over T F whole square plus higher order terms times 1 plus 5 by 8 pi square T over T F whole square plus higher order term.

(Refer Slide Time: 22:54)

$$\beta P = \left[\frac{g}{\lambda T} \frac{8}{15\sqrt{\pi}} (\beta \epsilon_F)^{5/2} \right] \left[1 - \frac{5}{12} \frac{1}{2} \left(\frac{1}{T F} \right)^{1/2} \dots \right] \left[\frac{1}{2m} \left(\frac{6n^2}{g} \right)^{1/2} \right]$$

$$\frac{g}{\lambda T} \frac{8}{15\sqrt{\pi}} (\beta \epsilon_F)^{5/2}$$

$$\frac{g}{\lambda T} \frac{8}{15\sqrt{\pi}} (\beta \epsilon_F)^{5/2} \times \beta \epsilon_F$$

$$\frac{g}{\lambda T} \frac{8}{15\sqrt{\pi}} \left(\frac{\beta \epsilon_F}{k} \right)^{3/2} \left(\frac{6n^2}{2m} \right)^{3/2} \frac{1}{g}$$

$$\frac{1}{\lambda T} \frac{6}{15} \left(\frac{\beta \epsilon_F}{k} \right)^{3/2} \left(\frac{6n^2}{2m} \right)^{3/2} \pi^{3/2} n$$

$$\frac{k^2}{2m} = \epsilon_F \quad \epsilon_F = \left(\frac{6n^2}{g} \right)^{1/2}$$

$$\frac{k^2}{2m} \left(\frac{6n^2}{g} \right)^{3/2} = \epsilon_F$$

$$\left(\frac{k^2}{2m} \right)^{3/2} \left(\frac{6n^2}{g} \right) = \epsilon_F^{3/2}$$

Now, let us look at this expression, I have g over lambda T 8 over 15 square root pi beta epsilon F raised to the power of 5 by 2 and I want to express this in terms of the number density n. So, even if you have forgotten how epsilon F depends on n there is always a way out.

Remember you can always start from this expression which is your ϵ_F and your Fermi wave vector k_F is defined as $6\pi^2 n$ over g raised to the power $1/3$. So, that I have h^2 square over twice m $6\pi^2$ square over n over g raised to the power of $1/3$ sorry I raised to the power $2/3$ is going to be your ϵ_F .

This part now I split, I write down g λT over 8 over 15 square root π times $\beta \epsilon_F$ raised to the power $3/2$ into $\beta \epsilon_F$. I mean this part I am interested in simplifying. Then, I have to look at ϵ_F to the power $3/2$ and ϵ_F to the power $3/2$ is h^2 square over twice m raised to the power $3/2$ and $6\pi^2$ square over n over g is going to be your ϵ_F raised to the power $3/2$.

So, let us substitute; I have g over λT 8 over 15 square root π h^2 square over twice m β to the power $3/2$, this raised to the power $3/2$. Now you should know where I am going. Things should be clear to you now and then I have $6\pi^2$ square n over g ; this part is just this thing. I have a $\beta \epsilon_F$ that multiplies this; g g gets cancelled out right.

And then, I have 1 over λT , I have 6 over 15 , I have βh^2 square over twice m raised to the power $3/2$. Now I have an additional factor 8 , which I am going to write down as 4 to the power $3/2$ and I have a π square; π to the power $3/2$. There is a π square in the numerator there is a square root π in the denominator that gives you π to the power $3/2$ and then finally, I have n .

(Refer Slide Time: 25:50)

$$\begin{aligned}
 & \frac{1}{\lambda_T} \frac{6}{15} \frac{\beta^2 \hbar^2}{2m} \left(\frac{4\pi}{2m} \right)^{3/2} n \\
 & \frac{1}{\lambda_T} \frac{6}{15} \frac{\beta^2 \hbar^2}{2m} \left(\frac{4\pi}{2m} \right)^{3/2} n \\
 & \frac{1}{\lambda_T} \frac{6}{15} \frac{\beta^2 \hbar^2}{2m} \left(\frac{4\pi}{2m} \right)^{3/2} n \\
 & \frac{1}{\lambda_T} \frac{6}{15} \frac{\beta^2 \hbar^2}{2m} \left(\frac{4\pi}{2m} \right)^{3/2} n \equiv \lambda_T \\
 & \frac{1}{\lambda_T} \frac{2}{5} \lambda_T n = \frac{2}{5} n \beta \epsilon_F \\
 & \beta P = \frac{2}{5} n \beta \epsilon_F \left[1 + \left(\frac{5}{8} - \frac{5}{24} \right) \left(\frac{T}{T_F} \right)^2 + \dots \right] \\
 & = \frac{2}{5} n \beta \epsilon_F \left[1 + \frac{5\pi^2}{12} \left(\frac{T}{T_F} \right)^2 + \dots \right]
 \end{aligned}$$

So, $\frac{1}{\lambda_T} \frac{6}{15} \frac{\beta^2 \hbar^2}{2m} \left(\frac{4\pi}{2m} \right)^{3/2} n$, and if you simplify this just this part this is $\frac{\beta^2 \hbar^2}{2m} \left(\frac{4\pi}{2m} \right)^{3/2} n$ raised to the power 3 by 2 times n, and if you simplify this just this part this is $\frac{\beta^2 \hbar^2}{2m} \left(\frac{4\pi}{2m} \right)^{3/2} n$ raised to the power 3 half and which you immediately identify as λ_T . So, your this whole expression then boils down to $\frac{1}{\lambda_T}$ this is going to be $\frac{2}{5}$ and then you have a λ_T and then n so, which is equal to $\frac{2}{5} n$.

Do not forget that you have an additional $\beta \epsilon_F$ lying outside so, you have this. So, therefore, your βP is $\frac{2}{5} n \beta \epsilon_F$. Now, I have to take care of this, this is to the leading order it is $1 + \left(\frac{5}{8} - \frac{5}{24} \right) \left(\frac{T}{T_F} \right)^2 + \dots$ plus higher order term.

So, 5 by 8 1 minus one-third that is 5 into 2 by 8 into 3 one gets it, 5 by 12; sorry. So, this is 2 by 5 n beta epsilon F 1 plus 5 by 12, there is a pi square somewhere; is it? Yes there is a pi square which we have missed, so we will T over T F whole square plus higher order term.

(Refer Slide Time: 28:01)

$$\begin{aligned}
 \beta P &= \frac{2}{5} n \beta \epsilon_F \left[1 + \left(\frac{5}{8} - \frac{5}{24} \right) \left(\frac{T}{T_F} \right)^2 + \dots \right] \\
 &= \frac{2}{5} n \beta \epsilon_F \left[1 + \frac{5}{12} \pi^2 \left(\frac{T}{T_F} \right)^2 + \dots \right] \\
 P_- &= \frac{2}{5} n \epsilon_F \left[1 + \frac{5}{12} \pi^2 \left(\frac{T}{T_F} \right)^2 + \dots \right] \\
 E &= \frac{3}{2} P V = \frac{3}{5} n V \epsilon_F \left[1 + \frac{5}{12} \pi^2 \left(\frac{T}{T_F} \right)^2 + \dots \right]
 \end{aligned}$$

$P_- = \frac{2}{5} n \epsilon_F$

P eta the pressure of the Fermi gas is n beta epsa F sorry n is 2 5 n epsa F 1 plus 5 by 12 pi square T by TF whole square plus. Now, this behavior is completely unlike an ideal classical gas, because in an ideal classical gas at zero temperature it has a zero pressure. But I know that at zero temperature the pressure of a Fermi gas, the eta is minus here so, we will put a p minus, we will put a P minus which is going to be 2 by 5 n times epsa F.

So, even at zero temperature the Fermi gas do exert certain amount of pressure, the pressure is not 0. Now, the energy is 3 by 2 P times V right, which means, I have three-fifth n times

the volume times $\epsilon_{psa} F 1 \text{ plus } 5 \text{ by } 12 \text{ pi square } T \text{ over } T F \text{ whole square plus higher order terms.}$

(Refer Slide Time: 29:38)

$$C_v = \left(\frac{\partial E}{\partial T} \right)_v = \frac{5}{2} N \epsilon_F \left[\frac{\pi^2}{12} \times \frac{k_B T}{T_F^2} + \dots \right]$$

$$= \frac{1}{2} N k_B T_F^2 \left(\frac{T}{T_F} \right)^2 + \dots$$

$$= \frac{1}{2} N k_B \left[\frac{T}{T_F} + O\left(\frac{T}{T_F} \right)^3 \right]$$

Specific heat is linear in temperature.

$$N \left(\frac{T}{T_F} \right)$$

$$\Delta E \sim N k_B T \left(\frac{T}{T_F} \right) \quad N k_B \frac{T^2}{T_F}$$

$$\sim N k_B \frac{T}{T_F}$$

Now, the specific heat is $\Delta E / \Delta T$ at constant volume, which is your C_v that is going to be $3 \text{ by } 5 N \epsilon_{psa} F \text{ times } 5 \text{ by } 12 \text{ into } 2 T \text{ over } T F \text{ square plus higher order terms.}$ So, a little more simplification gives me $N \epsilon_{psa} F \text{ is } K B.$ So, that this is going to be $3 \text{ by } 2$ so, a little more simplification gives me this cancels to give you 6, this cancels to give you 2 and the 5 5 cancels out, you have half $NK B$ and the $\epsilon_{psa} F \text{ is } K B T F.$ So, I will write down this as $K B T F \text{ time's } T \text{ over } T F \text{ square plus higher order terms.}$

So, that you have $NK B$ there is a π^2 which we have missed there has to be a π^2 here. There has to be a π^2 half $NK B \pi^2$ by $2NK B$ and then I have T of over $T F$ plus order $T \text{ over } T F \text{ whole cube, these are my higher order corrections.}$ So, clearly you see

that very close to the zero temperature the specific heat is linear in temperature and this is true for any arbitrary dimension you consider, we consider a three dimensional case, but in any arbitrary dimension you consider this is going to be true.

So, one can plot the specific heat with respect to temperature and you will get a result which will look like this and this is your. So, this is C_v over NK_B and this is the classical Dolong-Petite limit and here this part is going to be proportional to T over T_F a linear scaling.

Now, as we said that this is going to be linear in any arbitrary dimension that you consider, it does not depend on the dimension and we will see that this is in stark contrast to a Bose gas. But the reasoning is very very simple. Recall that at T equal to 0 the Fermi Dirac the occupation number looks like a step function. So, when you increase the temperature what you at most do is you basically have something which is like this.

So, you are exciting this many number of p particles and taking into a higher excited states over here. So, this fraction goes over here from here to here, the higher excited state. Now, that number of fraction is T over T_F times N and each of this particle carry an energy which is $K_B T$. So, that the total this is $NK_B T$ over times T over T_F , which is NK_B .

So, we will not write equal to but we will just say the change in the energy that you that happens from going from the here to here, the exciting because of thermal fluctuations that you have is T^2 over T_F . And therefore, your specific heat which is proportion which is basically $\Delta E \Delta T$. And therefore, the specific heat which is the derivative of this is will go as $NK_B T$ over T_F . And this result is surprisingly independent of the dimension of the system.
