**Relativistic Fermi Gas at T=0**

(Refer Slide Time: 00:23)

Ideal Fermi Gas  $\rightarrow$  Canonical Formalism  
 $\downarrow$   
Grand Canonical formalism  
 $\downarrow$   
T=0 Degenerate Fermi Gas  
Finite T but close to T=0  $\mu(T)$ ,  $U(T)$  and  $G(T)$   
Relativistic Fermi Gas at T=0:  
$$\epsilon = mc^2 \left[ 1 + \left( \frac{p}{mc} \right)^2 \right]^{1/2}$$

So, welcome back. Today having done all everything about ideal Fermi gas, we have looked at this ideal Fermi gas in the canonical formalism as well as in the grand canonical formalism.

So, we have looked at the T equal to 0 which is the degenerate Fermi gas and we have also looked at a finite temperature; finite temperature, but close to T equal to 0, we have seen how

$\mu$ , the chemical potential depends on this temperature, how the internal energy depends on the temperature and the specific heat depends on the temperature.

In the current lecture, what we are going to do is we are going to study a relativistic Fermi gas at  $T$  is equal to 0 so that we can write down this as  $mc^2 \sqrt{1 + \frac{p^2}{m^2 c^2}}$  half minus 1 and here, I have taken care of the rest mass, I have subtracted it out from my in this relation. So, I want to study how this Fermi gas is going to behave at  $T$  equal to 0.

$\downarrow$   
 Grand Canonical formalism  
 $\downarrow$   
 $T=0$  Degenerate Fermi Gas  
 Finite  $T$  but close to  $T=0$   $\mu(T)$ ,  $U(T)$  and  $G(T)$

Relativistic Fermi Gas at  $T=0$ :

$$\epsilon = mc^2 \left[ \sqrt{1 + \left(\frac{p}{mc}\right)^2} - 1 \right]$$

$\frac{p}{mc} \gg 1$   
 $mc^2 \left( \frac{p}{mc} - 1 \right)$   
 $cp - mc^2$

$\frac{p}{mc} \ll 1$   
 $1 + \frac{1}{2} \left( \frac{p}{mc} \right)^2 - 1$

So, before we go ahead with the calculation, let us just take two look at two limits of this.

(Refer Slide Time: 03:07)

4

$$\epsilon = mc^2 \left[ 1 + \left( \frac{p}{mc} \right)^2 \right]^{1/2} - 1$$

$$\frac{p}{mc} \gg 1 \quad \epsilon = mc^2 \left[ \left( \frac{p}{mc} \right)^2 - 1 \right]^{1/2} = mc^2 \left[ \frac{p}{mc} - 1 \right] \\ \therefore cp - mc^2$$

$$\frac{p}{mc} \ll 1 \quad \epsilon = mc^2 \left[ 1 + \frac{1}{2} \left( \frac{p}{mc} \right)^2 - 1 \right] = mc^2 \frac{1}{2} \frac{p^2}{m^2 c^2} = \frac{p^2}{2m} \\ \rightarrow \text{Non relativistic Gas.}$$

$$\eta = -1 \quad \ln Q_\gamma = -\eta \sum_k \ln (1 - \eta z e^{-\beta \epsilon_k})$$

First of all, one if you look at P over mc much much larger than 1, you will see that epsilon is mc square, this is the term which terminates so, P over mc whole square and then, I have raised to the power half minus 1 which becomes mc square P over mc minus 1 which is just c times p minus mc square, this is your rest mass energy as you already know and this is the case of an ultra relativistic gas .

In contrast, when you have P over mc as much much less than 1, then if you have mc square, I can expand this quantity in the brackets and term in a binomial series so that I am going to have P over mc square and keep up to this order minus 1 which gives you mc square times half p square over m square c square which gives you p square over twice m.

So, therefore, this gives you the non-relativistic gas and when you look at this energy expression, you are kind of doing both just have to figure out the limits when you finally, want to know the results.

(Refer Slide Time: 05:07)

14

$$\frac{p}{mc} \gg 1 \quad \epsilon = mc^2 \left[ \left[ \left( \frac{p}{mc} \right)^2 - 1 \right]^{1/2} - 1 \right] = mc^2 \left[ \frac{1}{\gamma} - 1 \right] \\ = cp - mc^2$$

$$\frac{p}{mc} \ll 1 \quad \epsilon = mc^2 \left[ 1 + \frac{1}{2} \left( \frac{p}{mc} \right)^2 - 1 \right] = mc^2 \sum \frac{1}{2} \frac{p^2}{m^2 c^2} = \frac{p^2}{2m} \\ \rightarrow \text{Non relativistic Gas.}$$

$$\eta = -1 \\ \ln Q_\eta = -\eta \sum_k \ln (1 - \eta z e^{\beta \epsilon_k}) \\ = -\eta$$

So, let us start with this, since it is a fermionic system, I have eta is equal to minus 1 and therefore, ln of Q eta, just recall was minus eta sum over k ln of 1 minus eta Z e to the power minus beta epsa which is minus eta.

(Refer Slide Time: 05:13)

$\bar{m}c$        $L$        $\rightarrow$  Non relativistic Gas.

$$\eta = -1$$

$$\ln Q_+ = -\eta \sum_k \ln(1 - \eta z e^{-\beta \epsilon_k})$$

$$\ln Q_- = \sum_k \ln(1 + z e^{-\beta \epsilon_k})$$

$$\ln Q_- = \frac{4\pi g V}{h^3} \int dp p^2 \ln(1 + z e^{-\beta \epsilon(p)})$$

$$= \frac{4\pi g V}{h^3} \left[ \frac{p^3}{3} \ln(1 + z e^{-\beta \epsilon(p)}) - \int dp \frac{p^3}{3} \frac{z e^{-\beta \epsilon(p)}}{1 + z e^{-\beta \epsilon(p)}} \frac{d(\beta \epsilon)}{dp} \right]$$

$\sum_k \rightarrow \frac{g V}{(2\pi)^3} \int d^3k$   
 $\frac{g V}{(2\pi)^3} \int d\epsilon k^2$   
 $\frac{V}{(2\pi\hbar)^3} \int dp p^2$

In this case, for a fermionic system, I know that this is going to be  $\ln$  of  $Q$  minus which is going to be sum over  $k$   $\ln$   $1 + z e$  to the power minus beta epsilon. We want to convert this sum into an integral over the energies so that we know that sum over  $k$  will go as  $v$  over  $2\pi$  cube integral of  $dk$  and this integral again we can write down this as in three-dimension, this is going to be  $k$  square. We will look at 3D system only.

Once you have this as 3D, I can bring, I can rewrite this equation as  $v$  over  $2\pi$  whole cube. Now, you see that here the momentum is in terms of  $p$  so, I want to write it down in terms of  $p$  which will give me  $dp$   $p$  square  $v$  over  $2\pi$   $h$  bar whole cube and I am going to have a factor  $g$   $v$  and a factor  $4\pi$  that is not over here, but a factor  $4\pi$  that will come over here. So, that  $\ln$  of  $Q$  minus becomes  $v$  over  $4\pi$   $g$   $v$  so, let us over  $h$  cube integral  $dp$   $p$  square  $\ln$  of  $1 + z e$  to the power minus epsilon of  $p$ .

I can integrate by parts that is what we have been doing so far so that this becomes  $gV$  over  $h$  cube  $p$  cube over 3  $\ln(1 + Ze^{-\beta\epsilon(p)})$ , this goes from 0 to infinity minus integral  $dp$   $p$  cube over 3 divided by the derivative of this term the log term with respect to  $p$  so, that is going to be  $Ze^{-\beta\epsilon(p)}$  and then, I have  $Ze^{-\beta\epsilon(p)}$  right and then, I have  $d/dp$  of  $-\beta\epsilon(p)$ . It is understood that  $\epsilon$  is a function of  $p$ .

(Refer Slide Time: 08:07)

4

$$\begin{aligned}
 \ln Q &= \frac{4\pi gV}{h^3} \int dp \frac{p^2 \ln(1 + Ze^{-\beta\epsilon(p)})}{\left(\frac{V}{2\pi h}\right)^3 \int dp p^2} \\
 &= \frac{4\pi gV}{h^3} \left[ \frac{p^3}{3} \ln(1 + Ze^{-\beta\epsilon(p)}) \Big|_0^\infty - \int_0^\infty dp \frac{p^3}{3} \frac{Ze^{-\beta\epsilon(p)}}{1 + Ze^{-\beta\epsilon(p)}} \frac{d(-\beta\epsilon)}{dp} \right] \\
 &= \frac{4\pi gV}{h^3} \frac{\beta}{3} \int_0^\infty dp \frac{p^3}{1 + Ze^{-\beta\epsilon}} \frac{d\epsilon}{dp} \\
 &= \frac{4\pi gV}{h^3} \frac{\beta}{3} \int_0^\infty dp \frac{p^3}{Ze^{-\beta\epsilon} + 1} \frac{d\epsilon}{dp}
 \end{aligned}$$

This term as you well know by now, it is going to be 0. So, I am left out with  $4\pi gV$  over  $h$  cube, the beta factor comes outside and this minus and this minus gives you a plus so, you have a beta over 3 and then, I have 0 to infinity  $dp$   $p$  cube  $Ze^{-\beta\epsilon}$  over 1 plus  $Ze^{-\beta\epsilon}$ . It is understood that beta, the  $\epsilon$  depends on  $p$ , the

momentum  $d\epsilon$   $dp$ . Let us write down this in the form that I know  $0$  to  $p$   $dp$   $p^3$  over  $Z$  inverse  $e$  to the power  $\beta \epsilon$  plus  $1$   $d\epsilon$   $dp$ .

(Refer Slide Time: 09:14)

$$= \frac{4\pi g V}{h^3} \frac{\beta}{3} \int_0^\infty dp \frac{p^3}{Z^{-1} e^{\beta \epsilon} + 1} \frac{d\epsilon}{dp}$$

$$\ln Q = \frac{4\pi g V}{h^3} \frac{\beta}{3} \int_0^\infty dp p^3 \langle n_p \rangle \frac{d\epsilon}{dp}$$

$$U = \sum_k \epsilon_k \langle n_k \rangle = \frac{4\pi g V}{h^3} \int_0^\infty dp p^2 \epsilon(p) \frac{1}{Z^{-1} e^{\beta \epsilon} + 1}$$

$$N = \sum_k \langle n_k \rangle = \frac{4\pi g V}{h^3} \int_0^\infty dp p^2 \frac{1}{Z^{-1} e^{\beta \epsilon} + 1}$$

And this I know that I can write down this as  $4\pi g V$  over  $h^3$   $\beta$  over  $0$  to infinity  $dp$   $p^3$   $\langle n_p \rangle$   $d\epsilon$   $dp$ . We have seen this in the standard results of a Fermi gas. So, this is going to be your  $\ln$  of  $Q$  minus. The energy is going to be sum over  $k$   $\epsilon_k$  average of  $n_k$  which is going to be  $4\pi g V$  over  $h^3$   $0$  to infinity  $dp$ , I will have  $\epsilon$  of  $p$ , there is going to be a  $p^2$  and then, I am going to have  $1$  over  $Z$  inverse  $e$  to the power  $\beta \epsilon$  plus  $1$ . So, these are the two results that we are primarily interested in.

If you notice, then you see I have not yet worked out the result for average of  $N$  so, where the total  $N$  is going to be sum over  $k$  average of  $n_k$  and this is going, this will give you the same

result that we obtained when we did the degenerate Fermi gas. So, this is going to be  $4\pi$  over  $h^3$  from 0 to infinity  $dp$   $p^2$   $1$  over  $z$  inverse  $e$  to the power  $\beta \epsilon_p$  plus 1 right.

(Refer Slide Time: 11:06)

$$U = \sum_k \epsilon_k \langle n_k \rangle = \frac{1}{h^3} \int_0^{p_f} 4\pi p^2 \frac{1}{z^{-1} e^{\beta \epsilon_p} + 1}$$

$$N = \sum_k \langle n_k \rangle = \frac{4\pi g V}{h^3} \int_0^{p_f} p^2 \frac{1}{z^{-1} e^{\beta \epsilon_p} + 1}$$

At  $T=0$ ,  $\Rightarrow N = \frac{4\pi g V}{h^3} \int_0^{p_f} p^2 dp = \frac{4\pi g V}{h^3} \frac{p_f^3}{3}$

$$\frac{3(N) h^3}{4\pi g V} = p_f^3$$

$$p_f = \left( \frac{3n h^3}{4\pi g} \right)^{1/3}$$

$p_f$   
 $k_f$   
 $\uparrow$   
 $\epsilon_f$

Now, we are looking at  $T$  equal to 0 so that this implies that I have a fermion so, all energy level up to the Fermi energy is filled up and corresponding to this Fermi energy, I know that I have a  $k_f$  and therefore, a momentum  $p_f$ . So, the idea is to figure out this momentum  $p_f$  and which I can do from this relation right so that would mean that  $N$  is going to be  $4\pi$  over  $h^3$  from 0 to  $p_f$   $dp$  over  $p^2$  that gives me  $4\pi$  over  $h^3$   $p_f^3$  divided by 3.

So, I have  $N h^3$  divided by 3  $N h^3$   $4\pi$  over  $h^3$  is going to be  $p_f^3$ . If you look up this, look at this expression, then you see I can take this some things out 4 by 3  $p_f^3$  over  $h^3$  right. So, this is the volume of a sphere of radius  $p_f$  and this essentially gives you the Fermi momentum  $p_f$ . So, that  $p_f$  is going to be  $N$  by  $v$  I can combine it into small  $n$  so, this

N and this v I can combine into a small n, I will be having 3 N h cube divided by 4 pi g raised to the power one-third. This result is identical to the value of k f which we got when we worked out the degenerate Fermi gas.

(Refer Slide Time: 13:28)

At 13:28

$$N = \frac{4\pi V}{h^3} \int_0^{p_f} p^2 dp = \frac{4\pi V}{h^3} \left[ \frac{p^3}{3} \right]_0^{p_f} = \frac{4\pi V}{3} \left( \frac{p_f}{h} \right)^3$$

$$\frac{3N h^3}{4\pi V} = p_f^3$$

$$p_f = \left( \frac{3N h^3}{4\pi V} \right)^{1/3}$$

$$p_f = \hbar k_f$$

$$\frac{3N h^3}{4\pi V} = \frac{\hbar^3 k_f^3}{(2\pi)^3}$$

$$k_f^3 = \frac{(2\pi)^2}{3} \frac{3N}{V}$$

$$k_f = \left( \frac{2\pi}{3} \right)^{1/3} \frac{3N}{V}$$

In fact, you can clearly see that if I write p f as h bar k f and substitute this relation over here, then I am going to have 3 n h cube 4 pi g is going to be h cube k f over 2 pi whole cube and you see h cube, h cube is going to cancelled away, I am going to have 2 into 2 pi instead of 4 pi so, one 2 pi factor cancels to give me 2 pi whole square so that k f is 2 pi whole square by 2 3 n g so, this is cube 3n sorry 3n divided by g.

This is 4 pi square so, this gives you 6 pi square n over g as k f whole cube, it is the same result that we have obtained before; that we have obtained before.

The reason they are same is because the energy  $\epsilon(p)$  does not enter this expression anywhere ok. What enters is only the dispersion relation and as long as the dispersion relation is same therefore, one has the same expression.

(Refer Slide Time: 14:50)

$$\langle n_p \rangle = \theta(\epsilon - \epsilon_f)$$

$$p_f = \left( \frac{3n}{4\pi g} \right)^{1/3}$$

$$p_f = \hbar k_f$$

$$\frac{3n}{4\pi g} = \frac{\hbar^3 k_f^3}{(2\pi)^3}$$

$$k_f^3 = \frac{(2\pi)^2}{3} \frac{3n}{\hbar^3}$$

$$k_f^3 = \frac{6\pi^2 n}{\hbar^3}$$

$$\ln Q = \frac{4\pi g V}{h^3} \beta \int_0^\infty dp p^3 \langle n_p \rangle \frac{d\epsilon}{dp}$$

$$\ln Q = \frac{4\pi g V}{h^3} \beta \int_0^{p_f} dp p^3 \frac{d\epsilon}{dp} \quad \text{At } T=0$$

$$U = \frac{4\pi g V}{h^3} \int_0^{p_f} dp p^2 \epsilon(p) \langle n_p \rangle = \frac{4\pi g V}{h^3} \int_0^{p_f} dp p^2 \epsilon(p) \quad \text{At } T=0$$

So, now, I have  $\ln$  of  $Q$  minus which was  $4\pi g V$  over  $h^3$  and then, I had  $\beta$  over  $3$   $dp p^3$   $\langle n_p \rangle \frac{d\epsilon}{dp}$ . Strictly at  $T$  is equal to  $0$ , I know that I have  $\langle n_p \rangle$  is going to be  $\theta(\epsilon - \epsilon_f)$  which essentially means that all momentum levels from  $0$  to  $p_f$  are filled just as we have seen for Fermi gas at degenerate Fermi gas at  $T$  is equal to  $0$  so that essentially, this limit which goes from  $0$  to infinity is now replaced by  $\beta$  over  $3$   $0$  to  $p_f$   $dp p^3 \frac{d\epsilon}{dp}$ , this is strictly at  $T$  is equal to  $0$  and we will use this later on.

The energy is going to be  $4\pi g V$  over  $h^3$   $0$  to infinity  $dp p^2 \epsilon(p)$  as the function of  $p$  and then, you have average of  $\langle n_p \rangle$  which again translates to  $4\pi g V$  over  $h^3$   $0$  to  $p_f$   $dp p^2 \epsilon(p)$

square epsilon p at T is equal to 0. One has to please let us go back and just check whether we have done it correctly otherwise, we have to do it again ok. This looks right to me.

Anyway, if we have anything, if we have made some mistake, we will come back and correct it. So, now, let us before we go ahead, I have to take a look at this derivative, and I have to use this.

(Refer Slide Time: 16:47)

$$\begin{aligned}
 v &= \frac{c}{\sqrt{1 - \frac{v^2}{c^2}}} \\
 E &= mc^2 \left[ \left( 1 + \frac{p^2}{m^2 c^2} \right)^{1/2} - 1 \right] \\
 E &= mc^2 [\cosh x - 1] \\
 \frac{dE}{dp} &= \frac{dE}{dx} \frac{dx}{dp} = mc^2 \sinh x \cdot \frac{1}{mc \cosh x} \\
 h\nu &= \frac{4\pi^2 \nu}{h^3} \int_0^{x_f} dp \, p^3 \frac{dE}{dp}
 \end{aligned}$$

$$\begin{aligned}
 p &= mc \sinh x \leftarrow p_f = mc \sinh x_f \\
 \frac{dp}{dx} &= mc \cosh x \rightarrow x_f = \sinh^{-1} \left( \frac{p_f}{mc} \right) \\
 1 + \left( \frac{p}{mc} \right)^2 &= 1 + \sinh^2 x = \cosh^2 x \\
 \sinh(x) &= \frac{e^x - e^{-x}}{2} \\
 \cosh(x) &= \frac{e^x + e^{-x}}{2}
 \end{aligned}$$

And energy, the relation in terms of momenta was not very simple we have 1 plus p over mc whole square this raised to the power half minus 1. So, we will make some substitutions to make our lives a little bit easier.

So, we go from a variable p to x such that p is mc sin hyperbolic x and therefore, one should note that dp dx which you are going to use frequently is mc cosh hyperbolic x and 1 plus p

over  $mc$  whole square is  $1 + \sinh^2 x$  which becomes  $\cosh^2 x$ , this becomes  $\cosh^2 x$  so that you have  $mc^2 \cosh x - 1$ , this is the relation.

$dE/dp$  which we are also going to need is going to be  $dE/dx \cdot dx/dp$ ,  $dE/dx$  is simply  $mc^2 \sinh x$  times we have calculated this, this becomes  $1/mc \cosh x$ . Please remember that  $\sinh x$  is  $(e^x - e^{-x})/2$  and  $\cosh x$  is  $(e^x + e^{-x})/2$ .

If you have  $n$ , if you have  $n$  sitting over here so, this becomes  $n^3 x$ ,  $n^3 x$ ,  $n^3 x$ ,  $n^3 x$ . So, this you can use to calculate derivatives if you are unfamiliar with this hyperbolic functions. So, with this in our hand, let us just first write down  $\ln Q$  minus which is  $4\pi g v / h^3 \beta$  from  $0$  to  $x_f$  where  $x_f$  is defined from this relation so, we will have  $p_f$  is going to be  $mc \sinh x_f$  which implies  $x_f$  is going to be  $\sinh^{-1}(p_f / mc)$ .

(Refer Slide Time: 19:52)

$$\frac{dE}{dp} = \frac{dE}{dx} \frac{dx}{dp} = mc^2 \sinh x \cdot \frac{1}{mc \cosh x} = c \tanh x$$

$$\sinh(x) = \frac{e^x - e^{-x}}{2}$$

$$\cosh(x) = \frac{e^x + e^{-x}}{2}$$

$$\ln Q = \frac{4\pi g v}{h^3} \beta \int_0^{x_f} dp \beta^3 \frac{dE}{dp}$$

$$= \frac{4\pi g v}{h^3} \beta \int_0^{x_f} dx \frac{dp}{dx} (mc \sinh x)^3 e^{-\beta mc \cosh x} \frac{\sinh x}{\cosh x}$$

$$= \frac{4\pi g v}{h^3} \beta \int_0^{x_f} dx mc \cosh x (mc)^3 \sinh^3 x \frac{\sinh x}{\cosh x}$$

So, this becomes  $dp$   $p$  cube  $d$   $\epsilon$   $dp$  which we write down as  $4 \pi g_V$  over  $h^3$   $\beta$ . Note that this is strictly at  $T$  is equal to 0, we are looking at the degenerate Fermi gas. So, I am sorry this in this case, we have the limit of  $p$   $f$ , we will write down the limit of  $x$   $f$  only after we have made the change of variables this is  $dp$   $dx$  times  $dx$  and this is  $p$  over sorry, this is going to be  $mc \sinh x$  whole cube,  $d \epsilon$   $dp$  is going to be let us look at this relation  $m$ ,  $m$  cancels out  $c$ ,  $c$  cancels out one factor so that you have  $c$  of tan hyperbolic of  $x$ .

So, we will write  $d \epsilon$   $dp$  as  $\sin$  hyperbolic of  $x$  divided by  $\cosh$  hyperbolic of  $x$ . So, that this becomes  $4 \pi g_V$  over  $h^3$   $\beta$  over 3 0 to  $x$   $f$   $dx$  and  $dp$   $dx$  is  $mc \cosh x$   $mc$  whole cube  $\sinh$  hyperbolic cube of  $x$  and then, you have  $\sinh x$  over  $\cosh x$ .

(Refer Slide Time: 21:32)

$$\begin{aligned}
 n_Q &= \frac{4\pi g_V}{h^3} \frac{\beta}{3} \int_0^{x_f} dp \, p^3 \frac{d\epsilon}{dp} \\
 &= \frac{4\pi g_V}{h^3} \frac{\beta}{3} \int_0^{x_f} dp \, dx \, (mc \sinh x)^3 \frac{\sinh x}{\cosh x} \\
 &= \frac{4\pi g_V}{h^3} \frac{\beta}{3} \int_0^{x_f} dx \, mc \cosh x \, (mc)^3 \sinh^3 x \frac{\sinh x}{\cosh x} \\
 \boxed{n_Q} &= \frac{4\pi g_V m^4 c^5}{h^3} \frac{\beta}{3} \int_0^{x_f} dx \, \sinh^4 x \\
 U &= \frac{4\pi g_V}{h^3} \int_0^{x_f} dp \, dx \, (mc \sinh x)^2 \cdot mc^2 (\cosh x - 1)
 \end{aligned}$$

This, this cancels out, I have  $m^4$  and there is a  $c$  factor here that one should not miss so,  $m^4$ ,  $m$  times  $m$  cube is  $m^4$  so, I am going to have  $4 \pi g_V m^4$  and I have 3 plus 1, 1 plus 3 is 4

plus 1 more is 5 so, I am going to have  $c^5 h^3$  over  $30$  to  $x^f dx \sinh^4$  of  $x$ . This is going to be  $\ln$  of  $Q$  minus.

The energy  $U$  is going to be  $4 \pi g v$  over  $h^3$  from  $0$  to  $x^f$ , now we are going to straight forward do it  $p$  square is  $mc \sinh x$  whole square and then, I have  $dp$  of  $p$  which in terms of this is going to be, in terms of  $x$  is going to be  $mc^2 \cosh x$  minus  $1$ .

(Refer Slide Time: 23:00)

$$\begin{aligned}
 U &= \frac{4\pi g v}{h^3} \int_0^{x^f} dx (mc \sinh x)^2 \cdot mc^2 (\cosh x - 1) \\
 &= \frac{4\pi g v}{h^3} \int_0^{x^f} dx mc^2 \sinh^2 x (\cosh x - 1) \\
 U &= \frac{4\pi g v m^4 c^5}{h^3} \int_0^{x^f} dx [\cosh^2 x \sinh^2 x - \sinh^2 x \cosh x] \\
 \sinh^4 x &= \left( \frac{e^x - e^{-x}}{2} \right)^4 = \frac{1}{2^4} [e^{4x} + e^{-4x} - 4e^{2x}e^{-2x} + 4e^{2x}e^{-3x} - 4e^{-2x}e^{3x}]
 \end{aligned}$$

$\frac{4!}{2!2!}$   
 $\frac{4!}{2!2!}$   
 $\frac{4!}{2!2!}$   
 $\frac{4!}{2!2!}$   
 $(x+y)^4 = x^4 + 4x^3y + 6x^2y^2 + 4xy^3 + y^4$

Now, so, let us quickly write down  $dx dp dx$  is going to be  $\cosh x mc$  whole square  $\sinh^2 x mc^2 \cosh x$  minus  $1$ . One factor of  $m$  here, two factor of  $m$  here so, cube  $4$ . So, you are going to have  $4 \pi g v m^4 c^5$ , the same factor  $h^3$  from  $0$  to  $x^f dx$  now,  $\cosh x$  times  $\cosh x$  gives you  $\cosh^2 x$   $\sinh^2 x$  and then, you are going to have minus  $\sinh^2 x \cosh x$ . So, this is the internal energy of this gas.

Now, the point is how do you integrate? It is a little bit tiresome, but one should be able to do it and we will do this exercises just try to see if you can follow the calculations, I mean you can try to repeat this calculations at you know at your own time.

$\sinh 4x$  is  $e$  to the power  $x$  minus  $e$  to the power  $-x$  by  $2$  raised to the power  $4$  which is if you recall that your binomial expansions  $(x+y)^4$  plus  $4c_1 x^3 y$  plus  $4c_2 x^2 y^2$  plus  $4c_3 x y^3$  plus  $y^4$ , we are just going to use this one. So,  $e$  to the power  $4x$  which is this term plus  $e$  to the power  $-4x$ ,  $4c_1$  is  $4$  factorial divided by  $3$  factorial which gives you a  $4$  here,  $x^3$  is  $e$  to the power  $3x$ ,  $y$  is  $e$  to the power  $-x$  so, you have  $-x$ .

Here,  $4c_2$  is  $4$  factorial divided by  $2$  factorial divided by  $2$  factorials. So,  $4$  factorial  $2$  factorial  $2$  factorial so,  $4$  into  $3$  by  $2$ .

If you want to calculate, this is the exact formula and you can see that this is actually  $6$ , but  $x^2$  is  $e$  to the power  $2x$ ,  $y^2$  is  $e$  to the power  $-2x$  so, we are just left out with  $6$ .  $4c_3$  is again going to be  $-4$  here of course, you are going to have  $e$  to the power  $x$   $e$  to the power  $-3x$  and this already you have taken over here so, our bracket closes here and then you have  $2$  to the power  $4$ .

(Refer Slide Time: 26:23)

$$\begin{aligned}
 \underline{\underline{\text{Sinh}^4 x}} &= \left( \frac{e^x - e^{-x}}{2} \right)^4 = \frac{1}{2^4} \left[ \overset{4x}{e^4x} - \overset{-4x}{e^{-4x}} - 4 \overset{3x}{e^{3x}} \overset{-x}{e^{-x}} + 6 \right. \\
 &= \frac{1}{16} \left[ (e^{4x} - e^{-4x}) - 4(e^{2x} + e^{-2x}) + 6 \right] \\
 &= \frac{1}{16} \left[ \frac{1}{4} \frac{d}{dx} (e^{4x} - e^{-4x}) - 4 \frac{1}{2} \frac{d}{dx} (e^{2x} - e^{-2x}) + 6 \frac{d}{dx} (x) \right] \\
 &= \frac{1}{16} \left[ \frac{d}{dx} \text{Sinh } 4x - 4 \frac{d}{dx} \text{Sinh } 2x + 6 \frac{d}{dx} (x) \right]
 \end{aligned}$$

2 to the power 4 is 1 over 16. Now, e to the power 4x. So, [FL] let us just first write down this and then we will minus 4 this is e to the power 2x plus e to the power minus 2x plus 6. Now, these are exponentials. So, I can equally write them as d dx of e to the power 4x minus 4x 1 by 4 right minus 4 d dx of e to the power 2x minus 2x divided by half plus d dx of 6 times d dx of x it is that simple.

So, 1 over 16, this is where the trick lie. Since, I am going to integrate this. So, if I write down as d derivative of the sub function, then it is much much easier for me. The one-fourth I can take 2 inside to write down this as sin hyperbolic of 4x, again I can take 2 inside to write down this as 4 d dx of sin hyperbolic of 2x plus 6 d dx of x nothing much you can do over here.

(Refer Slide Time: 27:56)

$$= \frac{1}{32} \frac{d}{dx} \left[ \frac{1}{32} \sinh 4x - \frac{1}{4} \sinh 2x + \frac{3}{8} x \right]$$

$$\int_0^{x_f} \cosh^4 x = \int_0^{x_f} \frac{d}{dx} g_1(x) = g_1(x_f)$$

$$\int_0^{x_f} \left[ \cosh^2 x \sinh^2 x - \sinh^2 x \cosh^2 x \right]$$

$$\int_0^{x_f} \left[ \frac{1}{4} \frac{d}{dx} (e^{4x} - e^{-4x}) - 2 \frac{dx}{dx} \right]$$

$$\cosh^2 x \sinh^2 x = \left( \frac{e^x + e^{-x}}{2} \right)^2 \left( \frac{e^x - e^{-x}}{2} \right)^2$$

$$= \frac{1}{16} \left[ (e^{2x} - e^{-2x})^2 \right]$$

$$= \frac{1}{16} \left[ e^{4x} + e^{-4x} - 2 \right]$$

$$= \frac{1}{16} \left[ \frac{1}{4} \frac{d}{dx} (e^{4x} - e^{-4x}) - 2 \frac{dx}{dx} \right]$$

So, this becomes 1 over 32, let us take the derivative out, the operator out and 1 by 16 inside so, I have 1 by 32 sin hyperbolic of 4x minus one-fourth sin hyperbolic of 2x plus 6 over 16, if I am going to do it divide cancel out by 2, then I will have 3 over 8 times x quite an elegant result. Similarly, so, therefore, let us just first write down 0 to x f dx, this is going to be 1 by 32 so, let me call this function let us say g 1 of x is integral dx 0 to x f d dx of g 1 of x which gives me g 1 of x f.

Let us look at the energy. Now, I have two terms over here 0 to x f dx cosh square x sinh square x minus I have sinh square x cosh x yeah. So, let us look at this.

So, I have 0 to. So, here let us do the calculation cosh square x sinh square x, this is going to be e to the power x plus e to the power minus x whole square times e to the power x minus x whole square so, which is going to be e to the power 2x, I was tempted to just write it down

as e to the power 2x minus e to the power minus sorry, this has to be 2 whole square this divided by 2 whole square.

So, overall, you have 1 by 16 times e to the power 4x plus e to the power minus 4x whole square because this you can write down a plus b times a minus b whole square. So, you have a square minus b square whole square, and this is going to be 1 over 16 e to the power 4x plus e to the power minus 4x minus of 2. So, again one write down; one writes this down as d dx of e to the power 4x minus e to the power of minus 4x 1 over 4 minus d dx of so, 2 times x.

(Refer Slide Time: 31:25)

$$\int_0^{x_f} \cosh^4 x = \int_0^{x_f} \frac{d}{dx} \left( \frac{e^x + e^{-x}}{2} \right)^2 = g(x_f)$$

$$\int_0^{x_f} \left[ \cosh^4 x - \sinh^2 x \cosh^2 x \right]$$

$$\int_0^{x_f} \cosh^2 x \sinh^2 x = g(x_f)$$

$$\int_0^{x_f} \cosh^2 x \sinh^2 x = \int_0^{x_f} d(\sinh x) \sinh^2 x$$

$$\cosh^2 x \sinh^2 x = \left( \frac{e^x + e^{-x}}{2} \right)^2 \left( \frac{e^x - e^{-x}}{2} \right)^2$$

$$= \frac{1}{16} \left[ e^{2x} - e^{-2x} \right]^2$$

$$= \frac{1}{16} \left[ e^{4x} + e^{-4x} - 2 \right]$$

$$= \frac{1}{16} \left[ \frac{1}{4} \frac{d}{dx} (e^{4x} - e^{-4x}) - 2 \frac{dx}{dx} \right]$$

$$= \frac{1}{16} \left[ \frac{1}{2} \frac{d}{dx} \left( \frac{e^{4x} - e^{-4x}}{2} \right) - 2 \frac{dx}{dx} \right]$$

$$= \frac{1}{32} \left[ \frac{d}{dx} \sinh 4x - \frac{1}{2} x^2 \right]$$

So, I have 1 by 16 half d dx of e to the power 4x minus e to the power minus 4x divided by 2 minus twice d dx of x. So, I will have 1 over 32; let us take the d dx outside, sin hyperbolic of 4x minus 1 by 8 times x. So, this is the integral.

So, therefore,  $\int_0^x \cosh^2 x \sinh^2 x \, dx$ , let us call this function as  $g_2$  of  $x$ , then I am going to have as simply  $g_2$  of  $x$ . This is easy  $\int_0^x \sinh^2 x \cosh x \, dx$ . Let us just change the order over here to write it down as  $\cosh x \sinh^2 x$  which means  $\int_0^x \sinh^3 x \, dx$ .

(Refer Slide Time: 33:00)

$$\int_0^x \cosh^2 x \sinh^2 x \, dx = \frac{1}{3} \sinh^3 x_f$$

$$\int_0^x \cosh^2 x \sinh^2 x - \sinh^2 x \cosh x \, dx = g_2(x_f) - \frac{1}{3} \sinh^3 x_f$$

$$= \frac{1}{16} \left[ \frac{1}{2} \frac{d}{dx} \left( \frac{e^{4x} - e^{-4x}}{2} \right) - \frac{1}{8} \frac{d}{dx} x \right]$$

$$= \frac{1}{16} \left[ \frac{1}{2} \frac{d}{dx} (2 \cosh 4x) - \frac{1}{8} \frac{d}{dx} x \right]$$

$$= \frac{1}{16} \left[ \frac{1}{2} \cdot 4 \sinh 4x - \frac{1}{8} \right]$$

$$= \frac{1}{4} \sinh 4x - \frac{1}{128}$$

$$Q_2 = \frac{4\pi^2 V m^4 c^5}{h^3} \frac{\beta}{3} g_2(x_f)$$

$$U = \frac{4\pi^2 V m^4 c^5}{h^3} \left[ g_2(x_f) - \frac{1}{3} \sinh^3 x_f \right]$$

And this is going to be  $\int_0^x \sinh^3 x \, dx$ . So, this integral then evaluates to  $\int_0^x \cosh^2 x \sinh^2 x \, dx - \int_0^x \sinh^2 x \cosh x \, dx$  is going to be  $g_2$  of  $x$  minus one-third  $\sinh^3 x$  that is the final answer good.

So, it is a very tedious algebra, I agree with you, but let us go ahead. Since, we have come so far let us push it forward a little bit.  $Q_2$  is going to be  $\frac{4\pi^2 V m^4 c^5}{h^3} \frac{\beta}{3}$  and the integral was integration of  $\sinh^4 x$  raised to the power 4

of  $x$  which we had was  $g_1$  of  $x_f$  and  $U$ , the energy was  $4\pi g_2$  over  $h^3$  minus one-third, I am going to have  $\sin^3$  of  $x_f$ .

(Refer Slide Time: 34:57)

$$\begin{aligned}
 \int_0^{x_f} \cosh x \sinh^2 x &= \int_0^{x_f} d(\sinh x) \sinh^2 x \\
 &= \frac{1}{3} \sinh^3 x_f \\
 \int_0^{x_f} (\cosh^2 x \sinh^2 x - \sinh^2 x \cosh x) &= g_2(x_f) - \frac{1}{3} \sinh^3 x_f \\
 &= \frac{1}{32} \left[ \frac{d}{dx} \left( \frac{1}{2} \cosh 4x - \frac{1}{8} x \right) \right] \\
 &= \frac{1}{16} \left[ \frac{1}{2} \frac{d}{dx} \left( \frac{e^{4x} - e^{-4x}}{2} \right) - \frac{1}{8} \frac{d}{dx} x \right] \\
 g_1(x_f) &= \frac{1}{32} \sinh 4x_f - \frac{1}{4} \sinh 2x_f + \frac{3}{8} x_f \\
 3g_2(x_f) &= \frac{3}{32} \sinh 4x_f - \frac{3}{8} x_f \\
 U &= \frac{4\pi^2 V}{h^3} m^4 c^5 \left[ g_2(x_f) - \frac{1}{3} \sinh^3 x_f \right] = \frac{4\pi^2 V}{h^3} \left[ \frac{3}{32} \sinh 4x_f - \sinh^3 x_f \right]
 \end{aligned}$$

Well, I can write down this as  $4\pi g_2$  over  $h^3$ ;  $3h^3$  since this also has a factor 3 and then, I am going to write down this as 3 times  $g_2$  of  $x_f$  minus  $x_f$  where  $g_1$  of  $x_f$  is going to be  $\frac{1}{32} \sinh 4x_f$  and then, I am going to have minus  $\frac{1}{4} \sinh 2x_f$  and I will going to have plus  $\frac{3}{8} x_f$ ,  $g_2$ , we will write down  $3g_2$  of  $x_f$  is going to be; this is going to be multiplied by this so, it is going to be  $\frac{3}{32} \sinh 4x_f$  minus  $\frac{3}{8} x_f$ .

(Refer Slide Time: 36:13)

4

$$\begin{aligned}
 h \nu &= \frac{4\pi^2 V m^4 c^5}{h^3} \frac{\beta}{3} g_3(x_f) \\
 U &= \frac{4\pi^2 V m^4 c^5}{h^3} \left[ g_2(x_f) - \frac{1}{3} \sinh^3 x_f \right] = \frac{4\pi^2 V}{3h^3} \left[ 3g_2(x_f) - \sinh^3 x_f \right] \\
 &= \frac{4\pi^2 V}{3h^3} g_3(x_f)
 \end{aligned}$$

$g_1(x_f) = \frac{1}{32} \sinh(4x_f) - \frac{1}{4} \sinh(2x_f) + \frac{3}{8} x_f$   
 $3g_2(x_f) = \frac{3}{32} \sinh(4x_f) - \frac{3}{8} x_f$   
 $g_3(x_f) = 3g_2(x_f) - \sinh^3 x_f$   
 $y_f = \sinh x_f$   
 $y_f \ll 1$   
 $y_f \gg 1$

$$\begin{aligned}
 \sinh 4x &= 2 \sinh 2x \cosh 2x \\
 &= 2 \sinh x \cosh x (\cosh^2 x + \sinh^2 x)
 \end{aligned}$$

And let us call this together as  $g_3$  of  $x$  which is equal to thrice  $g_2$  of  $x$  minus  $\sinh^3$  hyperbolic cube of  $x$  so that I have the result  $\frac{4\pi^2 V}{3h^3} g_3$  of  $x$  that is it. So, so far so good. A little bit more algebra is left out because what I want to do now is I know that  $\beta mc$  is going to be  $\sinh$  hyperbolic this over  $x$ .

So, I know this so, let us call this  $y$ . So, I want to express all this  $4x$  in terms of  $x$  because this is the primary variable of concern to me which is  $y$  and  $\sinh$  hyperbolic  $x$  which essentially because in the very beginning of the class, I had seen that  $\beta mc \ll 1$  corresponds to a non-relativistic gas and  $\beta mc \gg 1$  corresponds to an ultra-relativistic gas.

So, I will be looking for the limit of  $y \ll 1$  and  $y \gg 1$ , what is going to be the behaviour of this function and this function, but before even

we do that essentially, I have to express this  $4x$  f and  $2x$  f in terms of sinh hyperbolic of  $x$  f and that is not very easy difficult to do. So, sinh hyperbolic of  $4x$  is going to be twice sin hyperbolic  $2x$  cosh hyperbolic  $2x$ . This you can further break down as  $x$  cosh  $x$  cosh hyperbolic of  $2x$  is going to be cosh square  $x$  plus sinh square  $x$ .

(Refer Slide Time: 38:29)

$$\begin{aligned}
 \sinh 4x &= 2 \sinh 2x \cosh 2x \\
 &= 2 \sinh x \cosh x (\cosh^2 x + \sinh^2 x) \\
 &= 2 \sinh x \cosh x (1 + 2 \sinh^2 x) \\
 \sinh x &= 2 \sinh x \cosh x + 4 \sinh^3 x \cosh x \\
 \sinh 2x &= 2 \sinh x \cosh x
 \end{aligned}$$

$= \frac{4m_f v}{3h^3} q_3(x_f)$

$\frac{p_f}{mc}$ 
 $\sinh x_f$ 
 $y_f = \sinh x_f$ 
 $y_f \ll 1$ 
 $y_f \gg 1$

$mc$

If you want to write down predominantly in terms of sinh square  $x$ , you are going to just as cosine double for; double angle formulas to sin except that one the sin changes sinh square of  $x$  cosh  $x$  sin hyperbolic of  $x$  which is  $2x$  sin hyperbolic  $x$  cosh hyperbolic  $x$  plus  $4$  sinh hyper cube and then, you are going to have cosh  $x$ . So, this becomes your sinh  $x$  and sinh  $2x$  is going to be  $2$  sin hyperbolic of  $x$  cosh hyperbolic of  $x$  right. So, you can do this.

(Refer Slide Time: 40:20)

$$\sinh 2x = 2 \sinh x \cosh x$$

$$\int_0^{x_f} dx \sinh^4 x = \frac{1}{8} A(y_f) \quad \int_0^{x_f} dx [\cosh^2 x \sinh^2 x - \cosh x \sinh^2 x] = \frac{1}{24} B(y_f)$$

$$A(y) = \sqrt{1+y^2} (2y^3 - 3y) + 3 \sinh^{-1}(y)$$

$$B(y) = 8y^3 (\sqrt{1+y^2} - 1) + A(y)$$

$$\beta p V = \ln Q_+$$

$$\beta p V = \frac{4\pi^5 V m^4 c^5}{h^3} \beta \left[ \frac{1}{3} \frac{1}{8} A(y_f) \right]$$

$$U = \frac{4\pi^5 V m^4 c^5}{h^3} \frac{1}{24} B(y_f)$$

And in terms of this formulas, if you just do it, then  $\sinh 4x$  becomes  $A$  of  $y$  and  $0$  to  $x$   $\int dx$ . I had  $\cosh^2 x \sinh^2 x - \cosh x \sinh^2 x$  which was the expression which entered for the energy, I will call this so, this is going to be  $\frac{1}{8} A(y)$  and this is going to be  $\frac{1}{24} B(y)$ , where your  $A$  of  $y$  is going to be square root  $1 + y^2$  twice  $y^3$  minus  $3y$  plus  $3 \sin$  hyperbolic inverse of  $y$ . So, we will write down this as  $A$  of  $y$ .  $B$  of  $y$  is going to be  $B$  of  $y$ ;  $B$  of  $y$  is going to be  $8y^3 (1 + y^2 - 1) + A$  of  $y$ .

So, little bit complicated expression, but we have come to the fag end of this exercise and just we are done with this and we are left out with little bit more steps. So, one should note that  $\beta p V$  is going to be  $\ln$  of  $Q$  plus so that I have the expression  $\beta$  times pressure times volume is  $\frac{4\pi^5 V m^4 c^5}{h^3} \beta$  over  $3$  and then, I have  $\frac{1}{8}$  of  $A$  of  $y$  and the energy was  $\frac{4\pi^5 V m^4 c^5}{h^3} \frac{1}{24} B$  of  $y$ .

(Refer Slide Time: 43:14)

$$\int dx \sin x = -\cos(x) \quad \int_0^L \dots$$

$$A(y) = \sqrt{1+y^2} (2y^3 - 3y) + 3 \sin^{-1}(y) \quad \leftarrow \sin^{-1}(y) = \ln[y + \sqrt{1+y^2}]$$

$$B(y) = 8y^3 (\sqrt{1+y^2} - 1) + A(y)$$

$$\beta PV = \ln Q_T$$

$$\beta PV = \frac{4\pi g v m^4 c^5}{h^3} \beta \frac{1}{3} \frac{1}{\beta_2} A(y_f) = \frac{\pi g v m^4 c^5}{6 h^3} \beta A(y_f)$$

$$U = \frac{4\pi g v m^4 c^5}{h^3} \frac{1}{24} B(y_f) = \frac{\pi g v m^4 c^5}{6 h^3} B(y_f)$$

$$P = \frac{\pi g v m^4 c^5}{6 h^3} A(y_f)$$

So, this clearly simplifies to the 4, 4 gets cancelled over here to give you pi g v m 4 c 5 divided by 6 h cube beta A of y f and this is also going to give you pi g v m 4 c 5 6 h cube B of y f. So, that the thermodynamic pressure, therefore, takes care of the volume factors. So, let us just use this quickly to write down thermodynamic pressure of this gas is going to be pi g v m 4 c 5 over 6 h cube, the beta, beta cancels out, I will have A of y f.

So, either v also cancels out over here so, you have only pi g and this is the final expression that we have been trying to do where A y and B y are complicated functions which are given over here, but let us just check whether we have come at the right result.

(Refer Slide Time: 44:36)

$y_f \ll 1$

$A(y_f)$

$B(y_f)$

$$\rho = \frac{\pi^2 m^4 c^5}{6 h^3} A(y_f)$$

$y_f \gg 1$

$$A(y) \approx \frac{8}{5} y^5 - \frac{4}{7} y^7 + \dots \quad y \ll 1$$

$$B(y) \approx \frac{12}{5} y^5 - \frac{3}{7} y^7 + \dots \quad y \ll 1$$

$y_f \ll 1$

$$A(y) \approx 2y^4 - 2y^2 + \dots \quad y \gg 1$$

$$B(y) \approx 6y^4 - 8y^3 + \dots \quad y \gg 1$$

$u = \frac{\pi^2 v m^4 c^5}{6 h^3} y_f^5$

$\rho = \pi^2 m^4 c^5$

So, I am interested in  $y_f$  much much less than 1, what happens to  $A$  of  $y_f$  and  $B$  of  $y_f$ . Here, I have this sin hyperbolic inverse of  $x$  so, I am going to use the expression that sin hyperbolic  $y$  is going to be  $\log$  of  $y$  plus square root  $1$  plus  $y$  square. This I am going to use in the two limits, I will not work out the limits, but I will just write it down. It is very easy.

So, for  $y$  very very less than 1, this is  $8$  by  $5$   $y$  to the power  $5$  and then, you have  $4$  by  $7$   $y$  to the power  $7$  plus higher order terms when you have  $y$  much much less than 1 and you have  $B$  of  $y$  is going to be  $12$  by  $5$   $y$  to the power  $5$  minus  $3$  by  $7$   $y$  to the power  $7$  plus higher order terms. This is the first expansion that you are looking at.

For  $y$  much much larger than 1,  $A$   $y$ , this quantity is going to be we will use an approximate sign over here since this is an asymptotic expansion twice  $y^4$  minus twice  $y^2$  for  $y$

much much less than 1 and B y is going to be 6 y 4 minus 8 sorry this is cube no, this is y square and this is going to be cube for y larger than 1.

And this means that if I look over this expression for these two, for the first limit, I have U as pi g over 6 h cube b of y f right, I have this expression for U, b for y f much much less than 1 is going to be 12 over 5 y f to the power 5 and the pressure is going to be pi g sorry, I have missed out the m 4 c 5, it is going to be pi g m 4 c 5.

(Refer Slide Time: 48:01)

$$B(y) \approx \frac{12}{5} y^4 - \frac{8}{3} y^2 + \dots$$

$$K(y) \approx 2y^4 - 2y^2 + \dots \quad y \gg 1$$

$$b(y) \approx 6y^4 - 8y^3 + \dots \quad y \gg 1$$

$$y_f \ll 1 \quad \frac{U}{V} = \frac{\pi g}{6h^3} m^4 c^5 \frac{12}{5} y_f^5 \quad P = \frac{\pi g}{6h^3} m^4 c^5 \frac{8}{5} y_f^5$$

$$\frac{2}{3} \frac{U}{V} = \frac{\pi g m^4 c^5}{6h^3} y_f^5 \cdot \frac{2}{3} \frac{12}{5}$$

Let us in this expression, let us take the volume to the other side so that it is become clearer more easier to handle, I will have 6 h cube and it is going to be 8 over 5 y f to the power 5 right. So, two-third times U over V is going to be pi g over m 4 c 5 divided by 6 h cube y f raised to the power 5, 2 by 3 into twelve by 5 and does it help?

(Refer Slide Time: 48:58)

4

$$\begin{aligned}
 & y_f \gg 1 \\
 & \frac{U}{V} = \frac{\pi^2}{6h^3} m^4 c^5 \left(\frac{12}{5}\right) y_f^5 \\
 & \frac{U}{V} = \frac{\pi^2 m^4 c^5}{6h^3} \frac{8}{5} y_f^5 \quad p \sim \frac{1}{y_f^5} \rightarrow T=0 \\
 & \frac{3}{2} p = \frac{\pi^2 m^4 c^5}{6h^3} y_f^5 \cdot \frac{3}{2} \cdot \frac{8}{5} \\
 & = \frac{\pi^2 m^4 c^5}{6h^3} y_f^5 \left(\frac{12}{5}\right) \\
 & \frac{3}{2} p = \frac{U}{V}
 \end{aligned}$$

Now, from this expression, if you see if I multiply this by 3 by 2 p, this is going to be pi g m 4 c 5 over 6 h cube times there is a y f raised to the power 5 and then, I have 3 by 5 times 8 by 3 by 2 times 8 by 5, this gives me a 4, 3 times of 4 is 12 and you have the result pi g m 4 c 5 y f raised to the power 5 6 h cube you have 12 over 5.

Now, you clearly see that this factor is same as the factor over here so that you know that 3 by 2 pressure is going to be U by V which is the case for a non-relativistic gas as we have seen. So, once again we have done, everything is consistent, we should also know that the pressure is proportional to p f to the power 5 just as we found out when we did the degenerate Fermi gas.

4

$$b(y) \approx 6y^4 - 8y^3 + \dots \quad y \gg 1$$

$$y_f \ll 1 \quad \frac{U}{V} = \frac{\pi g}{6h^3} m^4 c^5 \left(\frac{12}{5}\right)^5 y_f^5 \quad P = \frac{\pi g m^4 c^5}{6h^3} \frac{8}{5} y_f^5 \quad P \sim h_f^5$$

$$\frac{3}{2} P = \frac{\pi g m^4 c^5}{6h^3} y_f^5 \frac{3}{2} \cdot \frac{8}{5} y_f^4 = \frac{\pi g m^4 c^5 y_f^5}{6h^3} \left(\frac{12}{5}\right)$$

$$\frac{3}{2} P = \frac{U}{V}$$

$$y_f \gg 1 \quad \frac{U}{V} = \frac{\pi g m^4 c^5}{6h^3} 2 \cdot y_f^4 \quad P = \frac{\pi g m^4 c^5}{6h^3} 6 y_f^4$$

Now, comes the other limit  $y$  much much larger than 1 and then, you have  $U$  over  $V$  which is going to be  $\pi g$  over  $m^4 c^5 6 h^3$  and then, I have 2 times  $y$  raised to the power 4, the pressure was  $\pi g m^4 c^5 6$  times  $h^3$  and this was 6 times  $y^4$ .

(Refer Slide Time: 50:57)

$$\frac{3}{2} P = \frac{\pi g m^4 c^5 y_f^5}{6 h^3} \cdot \frac{3}{2} \cdot \frac{8}{5} y_f^4$$

$$= \frac{\pi g m^4 c^5 y_f^9}{6 h^3} \left(\frac{12}{5}\right)$$

$$\frac{3}{2} P = \frac{U}{V}$$

$$P = \frac{\pi g m^4 c^5}{6 h^3} \cdot \frac{4}{5} y_f^4 \quad \frac{U}{V} = \frac{\pi g m^4 c^5}{6 h^3} \cdot \frac{6}{5} y_f^4$$

$$P \approx \frac{1}{3} \frac{U}{V} \quad \text{At } T=0$$

Now, in the opposite limit of  $y_f$  much much larger than 1, let us look at  $A y$ ,  $A y$  is leading term is  $2 y$  to the power 4 and therefore, pressure is going to be  $\pi g m^4 c^5$  over  $6 h^3$  2 times  $y_f$  raised to the power 4 and  $U$  by  $V$  is going to be  $\pi g m^4 c^5$  over  $6 h^3$  6 times  $y_f$  raised to the power 4.

From this, it is immediately clear these two factors that the pressure is going to be one-third  $U$  over  $V$  for as we expect for an ultra-relativistic gas. Also, we also note that the thermodynamic pressure is going to be proportional to the  $p f$  raised to the power 4 at  $T$  is equal to 0. So, here also one notes that this is at  $T$  is equal to 0.

Now, you might want to wonder that why did we go through all this trouble of doing this, but interestingly end of this finds application in astrophysics, particularly in dwarf stars, white

dwarfs, but that is for a more special field. So, we leave our discussion here at this point, you know how to handle such systems.
