Measurements: State Discrimination

The problem we are addressing in this lecture is the following. If we are given two states, ψ and ϕ , let us say they are qubit states, so they belong to the Hilbert space H_2 , and they are not orthogonal, means $\langle \psi | \phi \rangle$ inner product is not zero. Let us call it to be α , which is a complex number. Now, can we design a setup in which such that we can distinguish between the state ψ and ϕ . So, the problem can be stated like this.

We have an ensemble of quantum systems and each of that quantum system is either in the state ψ or in the state ϕ . And when the quantum system is given to us, we need to tell whether the state of the system was ψ or ϕ . If they were orthogonal states, then we could have chosen a measurement basis as ψ and ψ orthogonal and then we could have easily told whether the input state was ψ or it is orthogonal. But here it is not the case. So, the state of the ensemble which has a 50% probability of getting state ψ and 50% ϕ , the initial state of that can be written as a mixed state half times ψ outer product ψ and ϕ ϕ .

(Refer slide time: 2:31)

Distinguishing Non-orthogonal states:

$\rightarrow |\psi\rangle, |\phi\rangle \in H_2 \quad \langle \psi | \phi \rangle \neq 0 = \alpha \in \mathbb{C}$

$\rightarrow \rho = \frac{1}{2} [|\psi\rangle\langle\psi| + |\phi\rangle\langle\phi|]$

\rightarrow Probabilistic but unambiguous.

The slide also features a diagram of a measurement setup with a box and a meter, and the NPTEL logo in the top right corner.

This is the initial state of the ensemble. Now we need to find an experimental setup such that we perform measurement and we get a click in the plus side or minus side and by

looking at those clicks we can tell whether it's a psi state psi or phi. There are some restrictions and some conditions of this whole measurement setting that the result or the outcome or the distinguishability whether the input state was psi or phi can be probabilistic. But it should be unambiguous. So, it means for a given input quantum system, we can say the state is either psi or phi or the results are inconclusive. It should not be that we call the state to be psi, but it was not psi.

So, that is ambiguity. So, the result should be unambiguous, but it can be probabilistic. So, the first attempt can be the following. Let us design an experimental setting such that the basis in which we are performing measurement is the psi and psi orthogonal. So, if the input state is psi, then it will click in the psi in the plus click and if the input state is phi then it can click in plus or minus.

(Refer slide time: 5:14)

Handwritten notes on a grid background showing a quantum measurement setup and calculations. The setup shows an input line entering a box with two outputs labeled '+' and '-'. Below the box, it says 'psi' and 'phi'. The notes include: 'psi -> +', 'phi -> +, -', 'click in (-) -> phi', '(+) -> psi, phi'. Calculations show:
$$P_+ = \langle \psi | P_+ | \psi \rangle = \frac{1}{2} \langle \bar{\psi} | \psi \rangle^2 = \frac{1}{2} [\langle \psi | \psi \rangle + \langle \psi | \bar{\psi} \rangle] = \frac{1}{2} [1 + \langle \psi | \bar{\psi} \rangle]$$
 At the bottom, it says:
$$|\psi\rangle\langle\psi| + |\bar{\psi}\rangle\langle\bar{\psi}| = \mathbb{1}$$
 and
$$\rightarrow |\bar{\psi}\rangle\langle\psi| = \mathbb{1} - |\psi\rangle\langle\psi|$$

So, from here we can see that whenever we get a click in minus, this is the minus output for whenever we get a click in minus, then we know for sure it was state of phi but when we get click in plus Then it can be psi or phi. So, from this measurement setting, we can be sure when the click is in the minus, so, we know it is in state phi, but when the click is in plus, then we do not know whether it was in the state phi or psi. And the success rate will be the psi orthogonal rho psi orthogonal. Whenever there is a click in psi bar, psi orthogonal, then that is a successful case. This will be psi orthogonal phi mode square.

And this we can write as half, ϕ ψ orthogonal, ψ orthogonal ϕ . We know that ψ outer product ψ plus ψ orthogonal ψ orthogonal is identity. It means we can write $\bar{\psi} \psi$ as identity minus ψ and this can be written as half times $\phi \phi$ minus $\psi \psi$ mod square. So, we get p_s to be half times one minus $\psi \psi$ mod square which was α mod square. If we assume ψ to be \cos of θ over 2 \sin of θ over 2 and ϕ to be \cos of θ over 2 minus \sin of θ over 2 this is just single parameterization of the two states ψ and ϕ they are you can see they are not orthogonal in fact $\psi \phi$ is \cos of θ , so, α is \cos of θ and with this choice we get \sin θ over two as our success probability. We will get the same result if we choose a measurement basis, which is ϕ and ϕ orthogonal.

So, because there is no difference between ψ and ϕ and the success probability we get is \sin^2 θ over two in such kind of situations. Now, till now we have employed only the projective measurement in the basis, which will give us unambiguous result, but only with \sin^2 θ over two success rate. Now, can we do better than this when we go to POVM? This is what we will explore next. Let us say we have an ancilla and initially it is in the state 0 and the total state of a total Hilbert space is system tensor ancilla.

(Refer slide time: 6:13)

$$\rightarrow p_s = \frac{1}{2}(1 - \alpha^2) = \frac{\sin^2 \theta}{2}$$

$$|\psi\rangle = \begin{bmatrix} \cos \frac{\theta}{2} \\ \sin \frac{\theta}{2} \end{bmatrix} \quad |\phi\rangle = \begin{bmatrix} \cos \frac{\theta}{2} \\ -\sin \frac{\theta}{2} \end{bmatrix}$$

$$\langle \psi | \phi \rangle = \cos \theta$$

So, our total state is ψ tensor 0 or let me call ψ tensor 0 or it is ϕ tensor 0. So, the state is \cos θ over 2 0 0 plus minus \sin θ over 2 1 0 because we can write ψ and ϕ as \cos θ over 2 0 plus minus \sin θ over 2 1. So, this is the ψ initial of the system and ancilla. Now, let us say we can find a unitary which acts as follows. If we take it acts as \cos θ over 2 0 0, then it will give us \sin θ over 2 0 0 plus \cos θ over 2 1 1.

And if it acts on 1, 0, it will give us 1, 0. If it acts on 0, 1, it will give us 0, 1 and when it acts on 1, 1, we will get something orthogonal to this state. So, let us say such unitary exists. We know it will work. That is why I am giving you this unitary.

(Refer slide time: 8:07)

$$\Rightarrow |0\rangle : \text{ms} \otimes \text{MA}$$

$$|0\rangle \otimes |0\rangle, |0\rangle \otimes |1\rangle$$

$$|\psi\rangle = \cos\frac{\theta}{2}|00\rangle + \sin\frac{\theta}{2}|10\rangle$$

$$U|\psi\rangle = \cos\frac{\theta}{2}|00\rangle + \sin\frac{\theta}{2}|01\rangle + \sqrt{\cos\theta}|11\rangle$$

$$|00\rangle = |0\rangle$$

$$|01\rangle = |01\rangle$$

Then we will examine this unitary later on. So, what we have here is, when we apply U on psi initial, we get cos theta over 2 0 0 will go to sin theta over 2 0 0 plus root cos of theta 1 1 and plus minus sin theta over 2 will go to 1 0 will go to 1 0. We can write it as sine theta over 2, 0 plus minus 1, tensor 0. These are the first two terms, first and last term and the middle term, cos of theta, 1, 1, which can be written as 1, tensor 1. This 0 and this 1 is the state of ancilla and this is the state of system. Now, if we perform measurement on ancilla, then we can get 0 or 1. If outcome is 1, then the state of the system collapses to 1 and we have no idea whether this 1 came from the psi or phi.

If the ancilla is in 1, then system also goes to 1. But if the ancilla is in 0, then the system goes to sin theta over 2 is the overall factor. So, we multiply with root 2 and divide it by root 2. So, then the system collapses to 0 plus minus 1 over root 2. This is normalized state.

(Refer slide time: 10:17)

$$= \sqrt{\sin\frac{\theta}{2}} \left[\frac{|0\rangle + |1\rangle}{\sqrt{2}} \right] |0\rangle + \sqrt{\cos\theta} |1\rangle |1\rangle$$

Perform Measurement on Ancilla.

$$\{|0\rangle, |1\rangle\}$$

$$A \rightarrow |1\rangle : S \rightarrow |1\rangle$$

$$|0\rangle : \text{System} \rightarrow \frac{|0\rangle + |1\rangle}{\sqrt{2}}$$

And the plus sign is for psi and the minus sign is for phi. Now, if we perform, once we have 0 in the ancilla, then the system, we can perform the measurement on the system in the 0 plus minus 1 over root 2 basis. These are orthonormal basis. And then, if we get 0 plus 1, then we know it was psi. And if we get 0 minus 1, then it was phi.

So, in that way, once the ancilla collapses to 0, we have already succeeded. Then we can figure out what was the state of, what was the input state. So, here the probability that, the probability of failure is when we get 1 in the ancilla. So, the probability of failure is \cos of theta. And probability of success will be 1 minus \cos of theta, which becomes $2 \sin^2$ theta over 2.

(Refer slide time: 12:10)

$A \rightarrow |1\rangle : S \rightarrow |1\rangle$
 $|0\rangle : \text{System} \rightarrow \frac{|0\rangle + |1\rangle}{\sqrt{2}} \rightarrow |1\rangle$
 $\left\{ \frac{|0\rangle + |1\rangle}{\sqrt{2}} \right\} \quad |1\rangle, |0\rangle$
 $p_f = \cos^2 \theta$
 $p_s = 1 - \cos^2 \theta = 2 \sin^2 \frac{\theta}{2}$
 $= 4 \sin^2 \frac{\theta}{2} \cos^2 \frac{\theta}{2} = 2 \sin^2 \frac{\theta}{2} \left(\cos^2 \frac{\theta}{2} \right)$

If you remember that the probability of success from the projective measurement was \sin^2 theta over two and that can be written as $4 \sin^2$ theta over two \cos^2 theta over two that becomes $2 \sin^2$ theta over two times \cos^2 theta over two. So, the probability of success the \sin^2 theta over two which we got from the projective measurement that is a factor \cos^2 theta over two smaller than the probability of success we got in this new method of performing measurement. So, if we look at it carefully what we have done is we had a system and we wanted to distinguish between the two non-orthogonal states of that system. We couple it with another ancilla and the coupling unitary we found by some hit and trial method to be some strange unitary and that unitary is giving us the probability of success to be a significantly larger number than the one we got from the projective measurement. It doesn't matter how we got that unitary but that unitary is showing us that generalized measurements can give us results which are much better than the projected measurements. This is one example of showing the power of the projective measurement.

Now, how to arrive at this thing? We can look at the, we can revisit our concepts of the POVMs. So, let us say we consider a POVM with a first effect. to be some number a times psi orthogonal psi orthogonal, because we saw that psi whatsoever gives us the information about phi and phi whatsoever gives us the information about psi so we and there is no difference between psi and phi for us they are on equal footing for us then our we can assume the first effect as some number a times psi bar, psi bar, we will figure out what this a is. And the second POVM, second effect is a times phi orthogonal, phi orthogonal. And third is identity minus E1 minus E2.

(Refer slide time: 13:41)

$$E_1 = a |\bar{\psi}\rangle\langle\bar{\psi}|$$

$$E_2 = a |\bar{\phi}\rangle\langle\bar{\phi}|$$

$$E_3 = I - E_1 - E_2$$

Now we have to choose a in such a way that E3 is positive it is E3 is rank one and if we have those things then we can figure out the success probability and stuff like that. Now psi, we have chosen to be cos of theta over two sine of theta over two. From here, we can write psi bar which is orthogonal to psi to be sine of theta over two and minus cos of theta over two. Similarly, phi is cos of theta over 2 minus sine of theta over 2. From here, we can write phi bar to be sine of theta over 2 minus cos or cos of theta over 2. you can check that psi bar is orthogonal to psi and phi bar is orthogonal to phi. So, from here we can write E1 as a times sine squared theta over two cos squared theta over two sine theta over two cos theta over two minus and sine theta over two cos theta over two is minus sign and two will be with plus sign same just that these off diagonal elements are having different signs. So, E3, which is identity 1, 0, 0, 1 minus E1 minus E2. So, plus or minus A times where we add these two, we get 2 sine square theta over 2 to cos square theta over 2, 0, 0.

(Refer slide time: 15:10)

$$|\psi\rangle = \begin{bmatrix} \cos\frac{\theta}{2} \\ \sin\frac{\theta}{2} \end{bmatrix} \Rightarrow |\bar{\psi}\rangle = \begin{bmatrix} \sin\frac{\theta}{2} \\ -\cos\frac{\theta}{2} \end{bmatrix}$$

$$|\phi\rangle = \begin{bmatrix} \cos\frac{\theta}{2} \\ -\sin\frac{\theta}{2} \end{bmatrix} \Rightarrow |\bar{\phi}\rangle = \begin{bmatrix} \sin\frac{\theta}{2} \\ \cos\frac{\theta}{2} \end{bmatrix}$$

$$E_{1,2} = a \begin{bmatrix} \sin^2\frac{\theta}{2} & -\sin\frac{\theta}{2}\cos\frac{\theta}{2} \\ \sin\frac{\theta}{2}\cos\frac{\theta}{2} & \cos^2\frac{\theta}{2} \end{bmatrix}$$

(Refer slide time: 16:20)

$$E_3 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} - A \begin{bmatrix} 2 \sin^2 \frac{\theta}{2} & 0 \\ 0 & 2 \cos^2 \frac{\theta}{2} \end{bmatrix}$$

$$= \begin{bmatrix} 1 - 2A \sin^2 \frac{\theta}{2} & 0 \\ 0 & 1 - 2A \cos^2 \frac{\theta}{2} \end{bmatrix}$$

Diagram: A box representing a measurement process. An input state ρ enters from the left. Three measurement outcomes are shown on the right: $E_1 \rightarrow |\phi\rangle$, $E_2 \rightarrow |\psi\rangle$, and $E_3 \rightarrow \text{failure}$.

So, we get $1 - 2A \sin^2 \theta/2$ and $1 - 2A \cos^2 \theta/2$. Now hypothetically our setup is such that, formally our setup is such that we have our density matrix going in and output are the three measurement outcomes that is E_1 , E_2 and E_3 . We know when E_1 click and E_1 was just ψ orthogonal, then the input state was ϕ . When E_2 clicks, which is the ϕ orthogonal, then the input state was ψ . And when E_3 click, that is the failure.

So, the probability of E_3 , that is expectation value of E_3 will be, so, trace of E_3 times ρ and ρ is half times ψ plus ϕ and it turns out to be, so, the p_3 will be trace of identity minus a ψ orthogonal ψ orthogonal minus a ϕ orthogonal ϕ orthogonal times ρ . That will give us $1 - A \times \text{half times } \psi \text{ orthogonal } \phi \text{ mod square} - A \times \text{half times } \phi \text{ bar } \psi \text{ mod square}$ and these two numbers are same and these two numbers are $\sin^2 \theta/2$ and $1 - \sin^2 \theta/2$, so, total is $1 - \sin^2 \theta/2$. So, this is the failure probability. Now, from here, we see that we can make E_3 rank 1 by making either this element 0 or this element 0. So, it means if we make A to be $1/2 \sin^2 \theta/2$, then we get a E_3 to be rank 1 and if we choose A to be $1/2 \cos^2 \theta/2$, then E_3 is rank 1.

(Refer slide time: 17:50)

$$p_1 = \langle E_3 \rangle = \text{Tr}[E_3 \rho]$$

$$\rho = \frac{1}{2} [|+\rangle\langle +| + |\phi\rangle\langle\phi|]$$

$$E_3 = \text{Tr} \left[\left(1 - a |\phi\rangle\langle\phi| - a |\bar{\phi}\rangle\langle\bar{\phi}| \right) \rho \right]$$

$$= 1 - a \frac{1}{2} \langle \bar{\phi} | \phi \rangle^2 - \frac{a}{2} \langle \bar{\phi} | \phi \rangle^2$$

$$= 1 - a \frac{\sin^2 \theta}{2} - a \frac{\sin^2 \theta}{2}$$

$$= 1 - a \frac{\sin^2 \theta}{2}$$

We substitute both of them in this, then p_3 becomes $1 - \frac{\sin^2 \theta}{2}$. There is no $\frac{1}{2}$ here because there are half half, they cancel. So, $2 \times \frac{1}{2}$ and that is $1 - \frac{\sin^2 \theta}{2}$ can be written as $\frac{2 - \sin^2 \theta}{2}$ or $\frac{2 \cos^2 \theta}{2}$. This is $\frac{2 \cos^2 \theta}{2}$. If we choose A to be $\frac{1}{2 \cos^2 \theta}$, then p_3 becomes $1 - \frac{\sin^2 \theta}{2 \cos^2 \theta}$.

That will give us $1 - \frac{\sin^2 \theta}{2 \cos^2 \theta}$. That will be $\cos \theta$ and that will be $\cos \theta$. So, from here we can see that the choice A to be $\frac{1}{2 \cos^2 \theta}$ gives us a valid probability of, because probabilities cannot be negative and we are choosing θ to be in the range that $\cos \theta$ is positive. So, this is not a valid probability. So, we get the probability of failure P_3 to be $\cos \theta$ for a choice of A equals $\frac{1}{2 \cos^2 \theta}$.

(Refer slide time: 17:50)

$$a = \frac{1}{2 \sin^2 \frac{\theta}{2}} ; a = \frac{1}{2 \cos^2 \frac{\theta}{2}}$$

$$P_3 = 1 - \frac{\sin^2 \theta}{2 \sin^2 \frac{\theta}{2}} = 1 - \frac{4 \sin^2 \frac{\theta}{2} \cos^2 \frac{\theta}{2}}{2 \sin^2 \frac{\theta}{2}}$$

$$= 1 - 2 \cos^2 \frac{\theta}{2} = \cos \theta$$

$$P_3 = 1 - \frac{\sin^2 \theta}{2 \cos^2 \frac{\theta}{2}} = 1 - 2 \sin^2 \frac{\theta}{2} = \cos \theta$$

So, the probability of success becomes $1 - P_3$, which is $1 - \cos \theta$, which is $\frac{2 \sin^2 \theta}{2}$. This is precisely what we got when we chose that unitary, which looks strange at a moment, but it seems like that gives us the same result as we get when

we use the POVM technique. So, in that way using POVMs that too, three outcome POVM, we can find better distinguishability method of two non orthogonal states and the results are strikingly different from the one we had from projective measurement. We can implement here, if we just look at this POVM what we used, it is very interesting that E_1 , which is A , which was $\frac{1}{2} \cos^2 \theta$, $|\psi\rangle\langle\psi|$, E_2 which is $\frac{1}{2} \cos^2 \theta$, $|\bar{\psi}\rangle\langle\bar{\psi}|$, E_3 which is $\frac{1}{2} (1 - \cos^2 \theta)$, $|\psi\rangle\langle\bar{\psi}| + |\bar{\psi}\rangle\langle\psi|$, that is just 0, 0 with some coefficient and that coefficient is that will be $1 - \cos^2 \theta$. So, from here we can see that we have three unit vectors which are not normalized.

(Refer slide time: 21:48)

$$b_3 = 1 - b_2 = 1 - \cos^2 \theta = \sin^2 \theta$$

$$\rightarrow E_1 = \frac{1}{2 \cos^2 \theta} |\psi\rangle\langle\psi|$$

$$E_2 = \frac{1}{2 \cos^2 \theta} |\bar{\psi}\rangle\langle\bar{\psi}|$$

$$E_3 = 1 - \frac{1}{2 \cos^2 \theta} (|\psi\rangle\langle\bar{\psi}| + |\bar{\psi}\rangle\langle\psi|)$$

One is u_1 which is $\frac{1}{\sqrt{2} \cos \theta} |\psi\rangle$, u_2 which is $\frac{1}{\sqrt{2} \cos \theta} |\bar{\psi}\rangle$ and u_3 which is $\frac{1}{\sqrt{2} \sin \theta} (|\psi\rangle + |\bar{\psi}\rangle)$. With these three, we have these three vectors which are not orthogonal. But they have the property that $\sum_i u_i u_i^\dagger = I$, so, they form a POVM. This $u_i u_i^\dagger$ now by using Neumark's dilation theorem, we should be able to construct three three-dimensional vectors which are extension of the u_1, u_2, u_3 in such a way that they form an orthogonal basis. So, ω_i we can make as u_i direct sum c_i , c_i will be just a number because we already have two-dimensional vector, we want to make it three-dimensional vector and in such a way we choose c_i in such a way that this u_i, c_i are orthogonal basis. And this remains an exercise. For this given set of u_i 's find c_i 's in such a way w_i becomes orthonormal basis.

(Refer slide time: 22:28)

$$E_3 = 1 - \frac{1}{2 \cos^2 \theta} \left[|\psi\rangle\langle\psi| - |\phi\rangle\langle\phi| \right]$$

$$= (1 - \tan^2 \theta) |\psi\rangle\langle\psi|$$

$$|\psi\rangle = \frac{1}{\sqrt{2} \cos \theta} |\psi\rangle$$

$$|\psi\rangle = \frac{1}{\sqrt{2} \cos \theta} |\psi\rangle$$

$$|\psi\rangle = \frac{1}{\sqrt{1 - \tan^2 \theta}} |\psi\rangle$$

(Refer slide time: 23:59)

$$\sum_i |\psi_i\rangle\langle\psi_i| = I$$

Naimark dilation theorem.

$$\{ |\omega_i\rangle = |\psi_i\rangle \oplus |\psi_i\rangle \} \text{ ONB}$$

Now if we extend our Hilbert space of two vectors two dimensions to three dimensions and perform measurement with w_i in w_i basis then we will get the same result what we discussed in two different cases here. One with the unitary acting on the system and ancilla and other in terms of the POVM. And in this way, we can use generalized measurements to improve the distinguishability of non-orthogonal state.
